# Introduction

This book solves probability problems in GATE question papers.

# Chapter 1

## Axioms

## Chapter 2

# Distributions

2.1 Let  $\phi(\cdot)$  denote the cumulative distribution function of a standard normal random variable. If the random variable  $X$  has the cumulative distribution function

$$F(x) = \begin{cases} \phi(x), & x < -1 \\ \phi(x+1), & x \geq -1 \end{cases} \quad (2.1)$$

then which one of the following statements is true?

(a)  $P(X \leq -1) = \frac{1}{2}$

(b)  $P(X = -1) = \frac{1}{2}$

(c)  $P(X < -1) = \frac{1}{2}$

(d)  $P(X \leq 0) = \frac{1}{2}$

(GATE ST 2023)

**Solution: Gaussian**

Q function is defined

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^\infty e^{-\frac{u^2}{2}} du \quad (2.2)$$

From question and (2.2);

$$F_X(x) = \begin{cases} Q(-x), & x < -1 \\ 1 - Q(x+1), & x \geq -1 \end{cases} \quad (2.3)$$

From (2.3);

(a)

$$\Pr(X \leq -1) = F_X(-1) = 1 - Q(0) \quad (2.4)$$

$$= 0.5 \quad (2.5)$$

So Option A i.e.,  $P(X < -1) = \frac{1}{2}$  is correct

(b) The pdf of X can be defined in terms of cdf as

$$\Pr(X = b) = F_X(b) - \lim_{x \rightarrow b^-} F_X(x) \quad (2.6)$$

From (2.6);

$$\Pr(X = -1) = F_X(-1) - \lim_{x \rightarrow -1^-} F_X(x) \quad (2.7)$$

$$= 1 - Q(0) - Q(-(-1)) \quad (2.8)$$

$$= 0.341 \quad (2.9)$$

So Option B i.e.,  $P(X = -1) = \frac{1}{2}$  is incorrect

(c)

$$\Pr(X < -1) = \lim_{x \rightarrow -1^-} F_X(x) = F_X(-1) \quad (2.10)$$

$$= Q(-(-1)) \quad (2.11)$$

$$= 0.159 \quad (2.12)$$

So Option C i.e.,  $P(X < -1) = \frac{1}{2}$  is incorrect

(d)

$$\Pr(X \leq 0) = F_X(0) = 1 - Q(1) \quad (2.13)$$

$$= 0.8413 \quad (2.14)$$

So Option D i.e.,  $P(X \leq 0) = \frac{1}{2}$  is incorrect

Gaussian CDF plot of X is given in fig2.1

Figure 2.1:

2.2 Let  $X$  be a random variable with the probability density function  $f(x)$  such that

$$f(x) = \begin{cases} \frac{1}{2\sqrt{3}}, & -\sqrt{3} \leq x \leq \sqrt{3} \\ 0, & \text{otherwise} \end{cases} \quad (2.15)$$

Then the variance of  $X$  is?

(GATE XH-C1 2023)

**Solution:**

The mean of  $X$

$$\mu_X = \int_{-\infty}^{\infty} x f(x) dx \quad (2.16)$$

As the integrand is odd

$$\implies \mu_X = 0 \quad (2.17)$$

The variance of  $X$  is:

$$\sigma_X^2 = \mathbb{E} (X - \mu_X)^2 \quad (2.18)$$

From (2.17)

$$\implies \sigma_X^2 = \mathbb{E} (X^2) \quad (2.19)$$

$$= \frac{1}{2\sqrt{3}} \int_{-\sqrt{3}}^{\sqrt{3}} x^2 dx \quad (2.20)$$

$$= 1 \quad (2.21)$$

2.3 Two defective bulbs are present in a set of five bulbs. To remove the two defective bulbs, the bulbs are chosen randomly one by one and tested. If  $X$  denotes the minimum number of bulbs that must be tested to find out the two defective bulbs, then  $\Pr(X = 3)$  (rounded off to two decimal places) equals  
(GATE ST 2023)

**Solution:**

RV	Values	Description
A	0	1 <sup>st</sup> Bulb defective
	1	1 <sup>st</sup> Bulb non-defective
B	0	2 <sup>nd</sup> Bulb defective
	1	2 <sup>nd</sup> Bulb non-defective
C	0	3 <sup>rd</sup> Bulb defective
	1	3 <sup>rd</sup> Bulb non-defective

Table 2.1: Random variable declaration.

Here, the word "minimum" does not signify anything. Therefore we get

$$p_X(2) = p_{AB}(0, 0) \quad (2.22)$$

$$= \frac{2}{5} \times \frac{1}{4} \quad (2.23)$$

$$= \frac{1}{10} \quad (2.24)$$

$$p_X(3) = p_{ABC}(1, 0, 0) + p_{ABC}(0, 1, 0) + p_{ABC}(1, 1, 1) \quad (2.25)$$

$$= \frac{3}{5} \times \frac{2}{4} \times \frac{1}{3} + \frac{2}{5} \times \frac{3}{4} \times \frac{1}{3} + \frac{3}{5} \times \frac{2}{4} \times \frac{1}{3} \quad (2.26)$$

$$= \frac{3}{10} \quad (2.27)$$

$$p_X(4) = p_{ABC}(0, 1, 1) + p_{ABC}(1, 0, 1) + p_{ABC}(1, 1, 0) \quad (2.28)$$

$$= \frac{2}{5} \times \frac{3}{4} \times \frac{2}{3} + \frac{3}{5} \times \frac{2}{4} \times \frac{2}{3} + \frac{3}{5} \times \frac{2}{4} \times \frac{2}{3} \quad (2.29)$$

$$= \frac{6}{10} \quad (2.30)$$

Hence, The pmf of X is

$$p_X(k) = \begin{cases} 0 & k = 1 \\ \frac{1}{10} & k = 2 \\ \frac{3}{10} & k = 3 \\ \frac{6}{10} & k = 4 \\ 1 & k = 5 \end{cases} \quad (2.31)$$

2.4 Let  $X$  be a random variable with cumulative distribution function

$$F_X(x) = \begin{cases} 0 & \text{if } x < -1 \\ \frac{1}{4}(x+1) & \text{if } -1 \leq x < 0 \\ \frac{1}{4}(x+3) & \text{if } 0 \leq x < 1 \\ 1 & \text{if } x \geq 1 \end{cases} \quad (2.32)$$

Which one of the following statements is true?

(A)

$$\lim_{n \rightarrow \infty} \Pr \left( -\frac{1}{2} + \frac{1}{n} < X < -\frac{1}{n} \right) = \frac{5}{8} \quad (2.33)$$

(B)

$$\lim_{n \rightarrow \infty} \Pr \left( -\frac{1}{2} - \frac{1}{n} < X < \frac{1}{n} \right) = \frac{5}{8} \quad (2.34)$$

(C)

$$\lim_{n \rightarrow \infty} \Pr \left( X = \frac{1}{n} \right) = \frac{1}{2} \quad (2.35)$$

(D)

$$\Pr (X = 0) = \frac{1}{3} \quad (2.36)$$

(GATE ST 2023)

**Solution:**

$$f_X(x) = \begin{cases} 0 & \text{if } x < -1 \\ \frac{1}{4} & \text{if } -1 \leq x < 0 \\ \frac{1}{4} + \frac{1}{2}\delta(x) & \text{if } 0 \leq x < 1 \\ 0 & \text{if } x \geq 1 \end{cases} \quad (2.37)$$

(A)

$$\begin{aligned} \lim_{n \rightarrow \infty} \Pr \left( -\frac{1}{2} + \frac{1}{n} < X < -\frac{1}{n} \right) \\ = \lim_{n \rightarrow \infty} F_X \left( -\frac{1}{n} \right) - \lim_{n \rightarrow \infty} F_X \left( -\frac{1}{2} + \frac{1}{n} \right) \end{aligned} \quad (2.38)$$

$$= \lim_{n \rightarrow \infty} F_X \left( -\frac{1}{n} \right) - \lim_{n \rightarrow \infty} F_X \left( -\frac{1}{2} + \frac{1}{n} \right) \quad (2.39)$$

$$= \lim_{n \rightarrow \infty} \frac{1}{4} \left( -\frac{1}{n} + 1 \right) - \lim_{n \rightarrow \infty} \frac{1}{4} \left( -\frac{1}{2} + \frac{1}{n} + 1 \right) \quad (2.40)$$

$$= \frac{1}{8} \quad (2.41)$$

$\therefore (A)$  is not true.

(B)

$$\begin{aligned} \lim_{n \rightarrow \infty} \Pr \left( -\frac{1}{2} - \frac{1}{n} < X < \frac{1}{n} \right) \\ = \lim_{n \rightarrow \infty} F_X \left( \frac{1}{n} \right) - \lim_{n \rightarrow \infty} F_X \left( -\frac{1}{2} - \frac{1}{n} \right) \end{aligned} \quad (2.42)$$

$$= \lim_{n \rightarrow \infty} F_X \left( \frac{1}{n} \right) - \lim_{n \rightarrow \infty} F_X \left( -\frac{1}{2} - \frac{1}{n} \right) \quad (2.43)$$

$$= \lim_{n \rightarrow \infty} \frac{1}{4} \left( \frac{1}{n} + 3 \right) - \lim_{n \rightarrow \infty} \frac{1}{4} \left( -\frac{1}{2} - \frac{1}{n} + 1 \right) \quad (2.44)$$

$$= \frac{5}{8} \quad (2.45)$$

$\therefore (B)$  is true.

(C) From (2.37)

$$\lim_{n \rightarrow \infty} \Pr \left( X = \frac{1}{n} \right) = 0 \quad (2.46)$$

$\therefore (C)$  is not true.

(D) From (2.37)

$$\Pr(X = 0) = \frac{1}{2} \quad (2.47)$$

$\therefore (D)$  is not true.

Steps for the simulation of r.v  $X$ :

(a) Identify the point of discontinuity (0 here).

- (b) Define the simulation size for the simulation data set ( $\text{num\_sim}$ ).
- (c) Define the functions of CDF and PDF of  $X$ .
- (d) Find  $\Pr(X = 0)$  from the PDF of  $X$ .
- (e) For this simulation, the remaining numbers in  $[-1, 1)$  have probability of  $1 - \Pr(X = 0)$ .
- (f) Generate random sample in  $[-1, 1) - \{0\}$  of the size  $= \text{num\_sim} \times (1 - \Pr(X = 0))$ .
- (g) Generate sample containing only zeros of the size  $= \text{num\_sim} \times \Pr(X = 0)$ .
- (h) Combine all the generated samples to make a single sample and we generate the required r.v  $X$ .

Figure 2.2: CDF of X-(simulation vs actual)

2.5 Three unbiased coins were tossed. Provided that at least two outcomes are tails, the probability of having all three outcomes as tails is  
(GATE PI 2023)

**Solution:**

Parameter	value	description
$X_i$	1	first coin
	2	second coin
	3	third coin
$n$	3	number of coins
$p, q$	$\frac{1}{2}$	toss result in heads/tails
$Y$	$\sum_{i=0}^3 X_i$	three coins

Table 2.2: Definition of  $Y$  and parameters.

$$\Pr(Y = 3|Y \geq 2) = \frac{\Pr(Y \geq 2, Y = 3)}{\Pr(Y \geq 2)} \quad (2.48)$$

$$= \frac{\Pr(Y = 3)}{\Pr(Y \geq 2)} \quad (2.49)$$

$$= \frac{p_Y(3)}{1 - F_Y(1)} \quad (2.50)$$

$$p_Y(k) = {}^nC_k p^k q^{n-k} \quad (2.51)$$

$$= {}^3C_k \left(\frac{1}{2}\right)^k \left(\frac{1}{2}\right)^{3-k} \quad (2.52)$$

$$\Rightarrow p_Y(k) = \begin{cases} \frac{{}^3C_k}{8}; k = \{0, 1, 2, 3\} \\ 0; otherwise \end{cases} \quad (2.53)$$

$$F_Y(k) = \Pr(Y \leq k) \quad (2.54)$$

$$= \sum_{k=0}^k p_Y(k) \quad (2.55)$$

$$\Rightarrow F_Y(k) = \begin{cases} 0; k < 0 \\ \sum_{k=0}^k \frac{{}^3C_k}{8}; k = \{0, 1, 2, 3\} \\ 1; k > 3 \end{cases} \quad (2.56)$$

$$\Rightarrow \Pr(Y = 3|Y \geq 2) = \frac{\left(\frac{1}{8}\right)}{\left(\frac{1}{2}\right)} \quad (2.57)$$

$$= \frac{1}{4} \quad (2.58)$$

∴ The probability of having all three outcomes as tails is 0.25.

2.6 Let  $X$  be a random variable with probability density function

$$p_X(x) = \begin{cases} e^{-x} & \text{if } x \geq 0 \\ 0 & \text{otherwise} \end{cases} \quad (2.59)$$

For  $a < b$ , if  $U(a, b)$  denotes the uniform distribution over the interval  $(a, b)$ , then which of the following statements is/are true?

- (A)  $e^{-X}$  follows  $U(-1, 0)$  distribution
- (B)  $1 - e^{-X}$  follows  $U(0, 2)$  distribution
- (C)  $2e^{-X} - 1$  follows  $U(-1, 1)$  distribution
- (D) The probability mass function of  $Y = [X]$  is  $\Pr(Y = k) = e^{-k}(1 - e^{-1})$  for  $k = 0, 1, 2, \dots$ , where  $[X]$  denotes the largest integer not exceeding  $x$

(GATE ST 2023)

**Solution:** Let  $Y \sim U(a, b)$ , then

$$p_Y(y) = \begin{cases} \frac{1}{b-a} & a < y < b \\ 0 & \text{otherwise} \end{cases} \quad (2.60)$$

and for  $a < y < b$

$$F_Y(y) = \Pr(Y \leq y) \quad (2.61)$$

$$= \int_a^y \frac{1}{b-a} dy \quad (2.62)$$

$$= \frac{y-a}{b-a} \quad (2.63)$$

Similarly, for  $x \geq 0$

$$F_X(x) = \Pr(X \leq x) \quad (2.64)$$

$$= \int_0^x e^{-x} dx \quad (2.65)$$

$$= 1 - e^{-x} \quad (2.66)$$

$$(A) \ Y = e^{-X} = U(a, b)$$

for  $a < y < b$

$$F_Y(y) = \Pr(e^{-X} \leq y) \quad (2.67)$$

$$= \Pr(X \geq -\ln y) \quad (2.68)$$

$$= 1 - F_X(-\ln y) \quad (2.69)$$

$$= 1 - (1 - y) \quad (2.70)$$

$$= y \quad (2.71)$$

Comparing this with CDF of Uniform distribution, we obtain

$$a = 0, b = 1 \quad (2.72)$$

$$\therefore Y \sim U(0, 1) \quad (2.73)$$

$$(B) \ Y = 1 - e^{-X} = U(a, b)$$

for  $a < y < b$

$$F_Y(y) = \Pr(1 - e^{-X} \leq y) \quad (2.74)$$

$$= \Pr(e^{-X} \geq 1 - y) \quad (2.75)$$

$$= \Pr(X \leq -\ln(1 - y)) \quad (2.76)$$

$$= F_X(-\ln(1 - y)) \quad (2.77)$$

$$= 1 - (1 - y) \quad (2.78)$$

$$= y \quad (2.79)$$

$$\implies Y \sim U(0, 1) \quad (2.80)$$

$$(C) \ Y = 2e^{-X} - 1 = U(a, b)$$

for  $a < y < b$

$$F_Y(y) = \Pr(2e^{-X} - 1 \leq y) \quad (2.81)$$

$$= \Pr\left(X \geq -\ln\left(\frac{y+1}{2}\right)\right) \quad (2.82)$$

$$= 1 - F_X\left(-\ln\left(\frac{y+1}{2}\right)\right) = 1 - \left(1 - \frac{y+1}{2}\right) \quad (2.83)$$

$$= \frac{y+1}{2} \quad (2.84)$$

Comparing this with CDF of Uniform distribution, we obtain

$$a = -1, b = 1 \quad (2.85)$$

$$\therefore Y \sim U(-1, 1) \quad (2.86)$$

(D)  $Y = [X]$

$$\Pr(Y = k) = \Pr([X] = k) \quad (2.87)$$

$$= \Pr(k \leq X < k + 1) \quad (2.88)$$

$$= \int_k^{k+1} e^{-x} dx \quad (2.89)$$

$$= e^{-k} (1 - e^{-1}) \text{ for } k=0,1,2.. \quad (2.90)$$

(E) Generation of Random Variable  $X$  in C language

(i) `rand()` / `(double)RAND_MAX`:

This generates a random variable between 0 and `RAND_MAX` and divides it by `RAND_MAX` to obtain a uniform distribution between 0 and 1.

(ii) `-log(rand()) / (double)RAND_MAX` :

This transforms the uniform distribution between 0 and 1 into an exponential distribution by making the values vary from 0 to  $\infty$ .

(iii) Alternatively the Uniform distribution can be converted into Gaussian distribution using the Central Limit Theorem.

(iv) Gaussian is then converted into chi-square distribution with degree of freedom 2 which is similar to an exponential distribution.

Figure 2.3:  $e^{-X}$  vs.  $U(-1, 0)$   
 Graphs don't match,  $\therefore$  wrong option

Figure 2.4:  $1 - e^{-X}$  vs.  $U(0, 2)$   
 Graphs don't match,  $\therefore$  wrong option

Figure 2.5:  $2e^{-X} - 1$  vs.  $U(-1, 1)$   
 Graphs match,  $\therefore$  correct option

2.7 Question: Let  $X$  be a positive valued continuous random variable with finite mean  $\mu$ .

If  $Y = [X]$ , the largest integer less than or equal to  $X$ , then which of the following

statements is/are true?

(A)  $\Pr(Y \leq \mu) \leq \Pr(X \leq \mu)$  for all  $\mu \geq 0$

(B)  $\Pr(Y \geq \mu) \leq \Pr(X \geq \mu)$  for all  $\mu \geq 0$

(C)  $E(X) < E(Y)$

(D)  $E(X) > E(Y)$

(GATE ST 2023)

**Solution:** Given that  $X$  is a positive valued random variable and  $Y = [X]$ . So,

$$X = Y + Z \quad (2.91)$$

Here,  $Z$  is an uniform distribution.

$$Z \sim U[0, 1) \quad (2.92)$$

$$F_Z(x) = x \quad (2.93)$$

$$E(Z) = \frac{1}{2} \quad (2.94)$$

Consider

(a)

$$\Pr(Y \leq \mu) = \Pr(X - Z \leq \mu) \quad (2.95)$$

$$= \Pr(Z \geq X - \mu) \quad (2.96)$$

$$= E(1 - F_Z(X - \mu)) \quad (2.97)$$

$$= E(1 - X + \mu) \quad (2.98)$$

$$= 1 - E(X) + \mu \quad (2.99)$$

$$= 1 \quad (2.100)$$

From option (A), we have  $1 \leq \Pr(X \leq \mu)$ . Option (A) is wrong since probability can't be greater than 1.

(b)

$$\Pr(Y \geq \mu) = \Pr(X - Z \geq \mu) \quad (2.101)$$

$$= \Pr(Z \leq X - \mu) \quad (2.102)$$

$$= E(F_Z(X - \mu)) \quad (2.103)$$

$$= E(X - \mu) \quad (2.104)$$

$$= E(X) - \mu \quad (2.105)$$

$$= 0 \quad (2.106)$$

From option B, we have  $\Pr(X \leq \mu) \geq 0$ . Option (B) is correct.

(c)

$$E(Y) = E(X - Z) \quad (2.107)$$

$$= E(X) - E(Z) \quad (2.108)$$

$$= \mu - \frac{1}{2} \quad (2.109)$$

$$= E(X) - \frac{1}{2} \quad (2.110)$$

$E(X) > E(Y)$ . Option (D) is correct and (C) is wrong.

**Steps for Simulation:**

- (a) Taking  $n$  samples, Generate  $n$  exponential random variable( $X$ ) samples.
- (b) Generate  $n$  samples of  $Y = [X]$  by floor to every sample of  $X$ .
- (c) Find number of samples of  $X$  where  $X \leq \mu$  and  $X \geq \mu$  and divide with  $n$  to get  $\Pr(X \leq \mu)$  and  $\Pr(X \geq \mu)$  respectively.
- (d) Find number of samples of  $Y$  where  $Y \leq \mu$  and  $Y \geq \mu$  and divide with  $n$  to get  $\Pr(Y \leq \mu)$  and  $\Pr(Y \geq \mu)$  respectively.
- (e) Sum the  $n$  samples of  $X$  and  $Y$  and divide with  $n$  to get  $E(X)$  and  $E(Y)$ .

**Note:** At  $x \in \text{integers}$ ,  $Y = X$ , so, CDF curves of  $Y$  and  $X$  are same. At non-integers we can see some difference in CDF curves in  $X$  and  $Y$ .

2.8 In a diploid angiosperm species, flower colour is regulated by the R gene. RR and Rr genotypes produce red flowers, whereas the rr genotype produces white flowers. If two individual plants are randomly selected from a large segregating population of a genetic cross between RR and rr parents, the probability of both the plants producing red flowers is

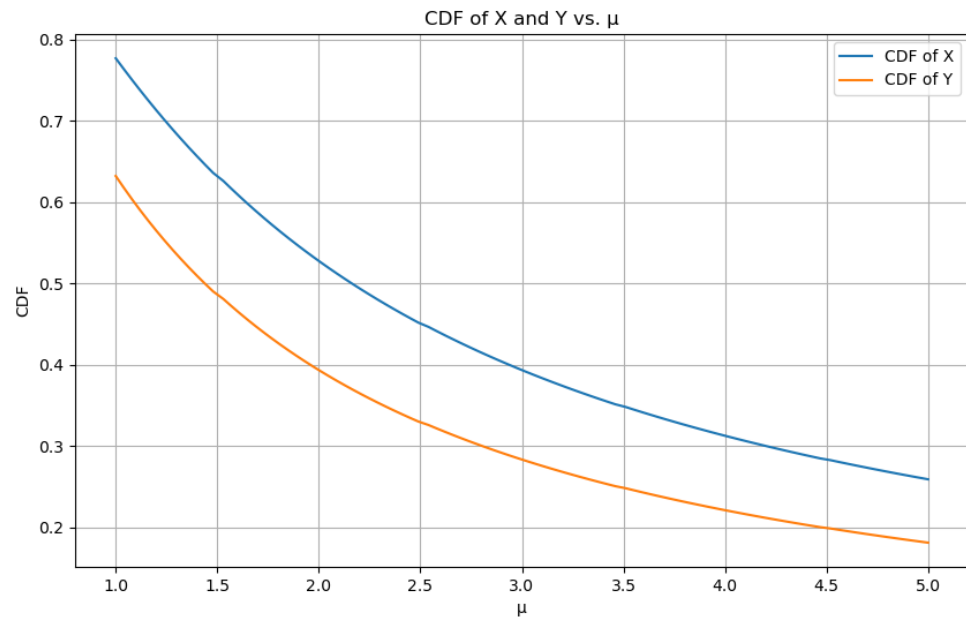

Figure 2.6: CDF'S of X and Y for varying  $\mu$  at  $x=1.5$

(GATE XL 2023)

**Solution:**

Gene	Representation
R	1
r	0

Table 2.4: Gene Representation.

For the parent genes:

Hence, we can see that it gives only Rr gene i.e.,10

For the children genes:

	1	1
0	10	10
0	10	10

Table 2.5: Gene of Parents.

	1	0
1	11	10
0	10	00

Table 2.6: Gene of Children.

$$p_X(k) = {}^nC_k p^k q^{n-k} \quad \forall k = 0, 1, 2 \quad (2.111)$$

$$= {}^2C_k \left(\frac{1}{2}\right)^k \left(\frac{1}{2}\right)^{2-k} \quad (2.112)$$

$$= {}^2C_k \left(\frac{1}{2}\right)^2 \quad (2.113)$$

we know that Red flower comes for RR and Rr i.e., 11 and 10

Therefore,

$$\Pr(X \leq 1) = 1 - \Pr(X = 2) \quad (2.114)$$

$$= 1 - \frac{1}{4} \quad (2.115)$$

$$= \frac{3}{4} \quad (2.116)$$

2.9 The frequencies for autosomal alleles  $A$  and  $a$  are  $p = 0.5$  and  $q = 0.5$ , respectively, where  $A$  is dominant over  $a$ . Under the assumption of random mating, the mating frequency among dominant parents is.

(GATE XL 2023)

RV	Values	Description
$X$	0	11
	1	10
	2	00

Table 2.7: Random varibale declaration

parameter	value
$n$	2
$p$	$\frac{1}{2}$
$q$	$\frac{1}{2}$

Table 2.8: Binomial parameters declaration

**Solution:** Given:  $A$  and  $a$  are two alleles where  $A$  is dominant one.

Let  $Y$  be a random variable depicting the number of dominant alleles in zygote( $AA, Aa, aA, aa$ )

Parameter	Value	Description
$A$	1	dominant allele
$a$	0	Recessive allele
$n$	2	number of Alleles
$p$	0.5	frequency of dominant one
$q$	0.5	frquency of recessive one
$Y$	0,1,2	Number of dominant allele in zygote

(a) Theory:

Using binomial which states that

$$\Pr(Y = i) = {}^nC_i(p)^i(q)^{(n-i)} \quad (2.117)$$

For the mating frequency among the dominant parents, both parents must have

Figure 2.7: Simulation vs Theoretical

atleast one dominant allele. The probability of getting atleast 1 dominant allele in parent zygote :

$$\Pr(Y \geq 1) = \Pr(Y = 1) + \Pr(Y = 2) \quad (2.118)$$

$$= {}^2C_1(p)(q) + {}^2C_2(p)^2(1) \quad (2.119)$$

$$= 2pq + p^2 \quad (2.120)$$

$$= 0.5 + 0.25 \quad (2.121)$$

$$= 0.75 \quad (2.122)$$

(b) Step for Simulation of Random variable  $Y$ :

- i. Define the simulation size for simulation data set.
- ii. Generate two different random distribution to get two different bernoulli showing  $A$  as 1 and  $a$  as 0 each having frequency of 0.5.
- iii. The two bernoulli data for parents will mate with each other to form a zygote containig 1's and 0's.
- iv. Add up two bernouli to generate binomial distrubition for random variable  $Y$  showing the number of 1's or dominant allele in zygote.
- v. Count up the cases where there is atleast one 1 to generate the simulated probability.

2.10 Let  $X$  be a random variable having poisson distribution with mean  $\lambda > 0$ . Then

$E\left(\frac{1}{1+X} \mid X > 0\right)$  equals

(a)  $\frac{1-e^{-\lambda}-\lambda e^{-\lambda}}{\lambda(1-e^{-\lambda})}$

(b)  $\frac{1-e^{-\lambda}}{\lambda}$

(c)  $\frac{1-e^{-\lambda}-\lambda e^{-\lambda}}{\lambda}$

(d)  $\frac{1-e^{-\lambda}}{\lambda+1}$

(GATE ST 2023)

**Solution:**

(A) Theory

$$X \sim Pois(\lambda) \quad (2.123)$$

$$\Pr(X = k) = e^{-\lambda} \frac{\lambda^k}{k!}; k \geq 0 \quad (2.124)$$

we know that

$$E(A|B) = \frac{E(A, B)}{\Pr(B)} \quad (2.125)$$

$$\Rightarrow E\left(\frac{1}{1+X} \middle| X > 0\right) = \frac{\sum_{k=1}^{\infty} \frac{1}{k+1} \Pr(X = k)}{\Pr(X > 0)} \quad (2.126)$$

$$= \frac{\sum_{k=1}^{\infty} \frac{1}{k+1} e^{-\lambda} \frac{\lambda^k}{k!}}{1 - \Pr(X \leq 0)} \quad (2.127)$$

$$= \frac{e^{-\lambda} \sum_{k=1}^{\infty} \frac{\lambda^k}{(k+1)!}}{1 - \Pr(X = 0)} \quad (2.128)$$

from equation (??)

$$= \frac{e^{-\lambda} \sum_{k=1}^{\infty} \frac{\lambda^k}{(k+1)!}}{1 - e^{-\lambda}} \quad (2.129)$$

Now simplifying Just the Summation

$$\Rightarrow \sum_{k=1}^{\infty} \frac{\lambda^k}{(k+1)!} \quad (2.130)$$

$$= \frac{1}{\lambda} \sum_{k=1}^{\infty} \frac{\lambda^{k+1}}{k+1} \quad (2.131)$$

Letting  $k+1 = m$ ,

$$\Rightarrow \frac{1}{\lambda} \sum_{m=2}^{\infty} \frac{\lambda^m}{m!} \quad (2.132)$$

We Know from Taylor series

$$e^x = \sum_{k=0}^{\infty} \frac{x^k}{k!} \quad (2.133)$$

$$\Rightarrow \frac{1}{\lambda} \sum_{m=2}^{\infty} \frac{\lambda^m}{m!} = \frac{1}{\lambda} (e^{\lambda} - 1 - \lambda) \quad (2.134)$$

Substituting back we get,

$$= \frac{e^{-\lambda}}{(1 - e^{\lambda})} \left( \frac{1}{\lambda} (e^{\lambda} - 1 - \lambda) \right) \quad (2.135)$$

$$= \frac{e^{-\lambda}}{\lambda(1 - e^{\lambda})} (e^{\lambda} - 1 - \lambda) \quad (2.136)$$

$$= \frac{1 - e^{-\lambda} - \lambda e^{-\lambda}}{\lambda(1 - e^{\lambda})} \quad (2.137)$$

(B) Simulation

- (i) In the code, it simulates the generation of RV  $X$  using the CDF of Poisson distribution.

$$F(x) = \sum_{k=0}^x e^{-\lambda} \frac{\lambda^k}{k!} \quad (2.138)$$

- (ii) initialize  $X = 0$
- (iii) initialize  $F = e^{-\lambda}$  which is  $F(0)$  of a poisson distribution
- (iv) generate a uniform random variable between 0 and 1
- (v) enter the loop that continues as long as  $u > F$

Inside the loop,

- (vi) Increment  $X$  by 1

- (vii) Add next term of Poisson pmf ( $\Pr(X = k + 1)$ ) to  $F(x)$
- (viii) the loop continues until  $u$  is no longer greater than  $F$ . At this point,  $X$  represents the generated value of the poisson random variable that follows the desired poisson distribution with mean parameter  $\lambda$ .
- (ix) Save all the values of poisson random variable  $X$  in pois.dat so to open it in python an plot the cdf graph
- (x) Then for the second part Check if the generated value of  $X$  is greater than 0. If  $X$  is greater than 0, calculate the value  $Y$  as  $\frac{1}{X+1}$  and add it to the sumY.Increment the validCount to keep track of valid  $X$  values.
- (xi) If validCount is greater than 0, calculate the estimate of the conditional expectation by dividing sumY by validCount.

Figure 2.8: Simulation Vs theoretical cdf of poisson distribution with  $\lambda = 9$

## Chapter 3

# Conditional Probability

# Chapter 4

## Random Variable

4.1 A cytoplasmic male-sterile female plant with the restorer (nuclear) genotype  $rr$  is crossed to a male-fertile male plant with the genotype  $RR$ . Both  $RR$  and  $Rr$  can restore the fertility, whereas  $rr$  cannot. When an  $F_1$  female plant with  $Rr$  genotype was test-crossed to a male-fertile male plant with the  $rr$  genotype, the percentage of the population that is male fertile would be? (GATE XL 2023)

**Solution:**  
Representing  $R$  and  $r$  as follows:

Gene	represent
R	1
r	0

Table 4.2: Table3:  $R=1,r=0$

On crossing between 00 and 11 we get:

	1	1
0	10	10
0	10	10

Table 4.4: Table1: Crossing btw  $RR$  and  $rr$

Which gives  $F_1$  as:

$$F_1 = \{10, 10, 10, 10\} \quad (4.1)$$

When  $F_1$  (10) is test-crossed with (00) we get:

	0	0
1	10	10
0	00	00

Table 4.6: Table2: Crossing btw 10 and 00

$$F_2 = \{10, 10, 00, 00\} \quad (4.2)$$

Probability that the population is male fertile(10) from (4.2) is given by:

$$\Pr(10) = \frac{1}{2} \quad (4.3)$$

$\therefore$  The percentage of the population that is male fertile would be 50%

## Chapter 5

# Moments

5.1 Suppose that  $X$  has the probability density function

$$f(x) = \begin{cases} \frac{\lambda^\alpha}{\Gamma(\alpha)} x^{\alpha-1} e^{-\lambda x} & \lambda > 0 \\ 0 & \text{otherwise} \end{cases} \quad (5.1)$$

where  $\alpha > 0$  and  $\lambda > 0$ . Which one of the following statements is NOT true?

- (a)  $E(X)$  exists for all  $\alpha > 0$  and  $\lambda > 0$
- (b) Variance of  $X$  exists for all  $\alpha > 0$  and  $\lambda > 0$
- (c)  $E(\frac{1}{X})$  exists for all  $\alpha > 0$  and  $\lambda > 0$
- (d)  $E(\ln(1 + X))$  exists for all  $\alpha > 0$  and  $\lambda > 0$

(GATE ST 2023)

**Solution:**

(a)

$$E(X) = \int_{-\infty}^{\infty} xp_X(x)dx \quad (5.2)$$

$$= \int_0^{\infty} x \frac{\lambda^\alpha}{\Gamma(\alpha)} x^{\alpha-1} e^{-\lambda x} \quad (5.3)$$

$$= \frac{\lambda^\alpha}{\Gamma(\alpha)} \int_0^{\infty} x^\alpha e^{-\lambda x} \quad (5.4)$$

$$(5.5)$$

since we know that

$$\int_0^{\infty} x^{\alpha-1} e^{-\lambda x} dx = \frac{\Gamma(\alpha)}{\lambda^\alpha} \quad \text{for } \lambda > 0, \alpha > 0 \quad (5.6)$$

$$E(X) = \frac{\lambda^\alpha}{\Gamma(\alpha)} \frac{\Gamma(\alpha+1)}{\lambda^{\alpha+1}} \quad (5.7)$$

Using the relation

$$\Gamma(x+1) = \Gamma(x)x \quad (5.8)$$

$$E(X) = \frac{\alpha}{\lambda} \quad (5.9)$$

Thus  $E(X)$  exists for all  $\alpha > 0$  and  $\lambda > 0$ .

(b)

$$Var(X) = E(X^2) - E(X)^2 \quad (5.10)$$

$$E(X^2) = \int_0^{\infty} x^2 \frac{\lambda^\alpha}{\Gamma(\alpha)} x^{\alpha-1} e^{-\lambda x} dx \quad (5.11)$$

$$= \int_0^{\infty} \frac{\lambda^\alpha}{\Gamma(\alpha)} x^{(\alpha+2)-1} e^{-\lambda x} dx \quad (5.12)$$

$$= \int_0^{\infty} \frac{1}{\lambda^2} \frac{\lambda^{\alpha+2}}{\Gamma(\alpha)} x^{(\alpha+2)-1} e^{-\lambda x} dx \quad (5.13)$$

$$E(X^2) = \int_0^{\infty} \frac{\alpha(\alpha+1)}{\lambda^2} \frac{\lambda^{\alpha+2}}{\Gamma(\alpha+2)} x^{(\alpha+2)-1} e^{-\lambda x} dx \quad (5.14)$$

using the density of the gamma distribution, we get

$$E(X^2) = \frac{\alpha(\alpha+1)}{\lambda^2} \quad (5.15)$$

$$Var(X) = \frac{\alpha^2 + \alpha}{\lambda^2} - \frac{\alpha^2}{\lambda} \quad (5.16)$$

$$= \frac{\alpha}{\lambda^2} \quad (5.17)$$

Thus, Variance of  $X$  exists for all  $\alpha > 0$  and  $\lambda > 0$

(c)

$$E\left(\frac{1}{X}\right) = \int_0^{\infty} \frac{1}{x} \frac{\lambda^\alpha}{\Gamma(\alpha)} x^{\alpha-1} e^{-\lambda x} dx \quad (5.18)$$

$$= \frac{\lambda^\alpha}{\Gamma(\alpha)} \int_0^{\infty} x^{\alpha-2} e^{-\lambda x} dx \quad (5.19)$$

For this,  $\alpha > 1$  is a must condition. Hence C is not a correct option. Hence C is the answer.

(d) For  $E(\ln(1 + X))$ ,

$$E(\ln(1 + X)) = E(X) - \frac{E(X^2)}{2} + \frac{E(X^4)}{4} - .. \quad (5.20)$$

We write the general expression for  $E(X^n)$

$$E(X^n) = \frac{(\alpha)(\alpha + 1) \dots (\alpha + n - 1)}{\lambda^n} \quad (5.21)$$

So by applying the ratio test to check the convergence of the sequence

$$\lim_{n \rightarrow \infty} \left| \frac{a_{n+1}}{a_n} \right| = L \quad (5.22)$$

$$\left| \frac{E(X^{n+2})}{E(X^n)} \right| = \frac{\frac{(\alpha)(\alpha+1)\dots(\alpha+n+1)}{\lambda^{n+2}}}{\frac{(\alpha)(\alpha+1)\dots(\alpha+n-1)}{\lambda^n}} \quad (5.23)$$

$$= \frac{(\alpha + n)(\alpha + n + 1)}{\lambda^2} \quad (5.24)$$

$$\lim_{n \rightarrow \infty} \left| \frac{E(X^{n+2})}{E(X^n)} \right| = \infty \quad (5.25)$$

Thus  $E(\ln(1 + X))$  generates a divergent function and hence  $E(\ln(1 + X))$  does not exist for all  $\alpha > 0$  and  $\lambda > 0$ .

5.2 The signal-to-noise ratio (SNR) of an ADC with a full-scale sinusoidal input is given to be 61.96 dB. The resolution of the ADC is

(GATE EC 2023)

**Solution:**

Variable	Defination
$T$	Time Period
$f$	Frequency
$A$	Amplitude
$P_S$	Signal Power
$P_N$	Noise Power
$q$	Quantization step size
$n$	No of bits
$Y$	Quantization Error

Figure 5.1: Quantization of Sinusoidal Signal

(a) Signal Power:

The power of a continuous-time signal is defined as the average value of the square of the signal over a certain time interval. For a sinusoidal signal  $x(t) =$

$A \sin(2\pi ft + \phi)$ , the power ( $P_S$ ) is calculated as:

$$P_S = \lim_{T \rightarrow \infty} \frac{1}{T} \int_{-\frac{T}{2}}^{\frac{T}{2}} |x(t)|^2 dt \quad (5.26)$$

where  $\phi$  is the phase of the signal.

$$P_S = \lim_{T \rightarrow \infty} \frac{1}{T} \int_{-\frac{T}{2}}^{\frac{T}{2}} |A \sin(2\pi ft + \phi)|^2 dt \quad (5.27)$$

$$P_S = \lim_{T \rightarrow \infty} \frac{1}{T} \int_{-\frac{T}{2}}^{\frac{T}{2}} A^2 \sin^2(2\pi ft + \phi) dt \quad (5.28)$$

$$P_S = \lim_{T \rightarrow \infty} \frac{1}{T} \int_{-\frac{T}{2}}^{\frac{T}{2}} A^2 \cdot \frac{1 - \cos(4\pi ft + 2\phi)}{2} dt \quad (5.29)$$

$$P_S = \frac{1}{2} \lim_{T \rightarrow \infty} \frac{1}{T} \int_{-\frac{T}{2}}^{\frac{T}{2}} A^2 dt - \frac{1}{2} \lim_{T \rightarrow \infty} \frac{1}{T} \int_{-\frac{T}{2}}^{\frac{T}{2}} A^2 \cos(4\pi ft + 2\phi) dt \quad (5.30)$$

$$P_S = \frac{1}{2} \cdot A^2 - 0 \quad (5.31)$$

$$P_S = \frac{A^2}{2} \quad (5.32)$$

$$(5.33)$$

Here,  $A=1$ , so:

$$P_S = \frac{1}{2} \quad (5.34)$$

(b) Noise Power:

No of Quantization levels is given by  $2^n$ , Where n is resolution or no of bits.

Distance between any two Quantization levels = Quantization step

(No of Quantization levels)\*(Quantization step) = Peak Distance (Refer to Fig 1)

$$q = \frac{\text{Peak distance}}{2^n} = \frac{1 - (-1)}{2^n} = \frac{2}{2^n} = 2^{-(n-1)} \quad (5.35)$$

We know, quantization error has a maximum value of plus or minus half the step size, so

$$|Y| \leq \frac{q}{2} \text{ and therefore, } |Y| \leq 2^{-n} \quad (5.36)$$

For a large enough number of quantization steps, the probability density function of the quantization error tends toward being flat 1. Pdf of error (Y) of quantization is defined as

$$p_Y(y) = \begin{cases} \frac{1}{q}, & \text{if } -\frac{q}{2} \leq y \leq \frac{q}{2} \\ 0, & \text{otherwise} \end{cases} \quad (5.37)$$

Figure 5.2: plot of pdf of Quantization Error

So, we can calculate its mean power or variance as the 2nd moment of its distribution.

Since, the distribution of error is uniform hence  $E[Y]=0$ .

$$E(Y) = \int_{-\frac{q}{2}}^{\frac{q}{2}} p_Y(y) y \, dy \quad (5.38)$$

$$= \frac{1}{q} \cdot \frac{1}{2} \left( \left( \frac{q}{2} \right)^2 - \left( -\frac{q}{2} \right)^2 \right) \quad (5.39)$$

$$= \frac{1}{q} \cdot \frac{1}{2} (0 - 0) \quad (5.40)$$

$$= 0 \quad (5.41)$$

$$E[Y^2] = \int_{-\frac{q}{2}}^{\frac{q}{2}} p_Y(y) y^2 dy \quad (5.42)$$

$$= \frac{1}{q} \cdot \frac{1}{3} \left( \left( \frac{q}{2} \right)^3 - \left( -\frac{q}{2} \right)^3 \right) \quad (5.43)$$

$$= \frac{1}{3q} \cdot \frac{q^3}{4} \quad (5.44)$$

$$= \frac{q^2}{12} \quad (5.45)$$

$$(5.46)$$

On putting  $q = 2^{-(n-1)}$ , we have:

$$E[Y^2] \approx \frac{2^{-2n}}{3} \quad (5.47)$$

$$P_Y \approx \frac{2^{-2n}}{3} \quad (5.48)$$

$$P_N \approx \frac{2^{-2n}}{3} \quad (5.49)$$

$$(5.50)$$

Thus, an ideal ADC would have a signal-to-noise ratio

$$SNR = \frac{P_S}{P_N} = 1.5 \cdot 2^{2n} \quad (5.51)$$

or, expressed in decibels,

$$SNR = 10 (\log_{10}(1.5 \cdot 2^n)) \quad (5.52)$$

$$= 10 (\log_{10}(1.5) + \log_{10}(2^{2n})) \quad (5.53)$$

$$= 10 (0.176 + 2n \cdot 0.3010) \quad (5.54)$$

$$= 1.76 + 6.02n \quad (5.55)$$

Substituting value of  $SNR$

$$61.96 = 1.76 + 6.02n \quad (5.56)$$

$$n = \frac{61.96 - 1.76}{6.02} \quad (5.57)$$

$$= \frac{60.2}{6.02} \quad (5.58)$$

$$= 10 \quad (5.59)$$

So, the resolution of the ADC is approximately 10 bits.

Simulation Steps :-

- i. Initialize the simulation parameters, including the given SNR in dB (which is 61.96 dB) and signal power ( $P_s$ ) (which is 0.5), and create an array of quantization error values ( $q$ -values) to test.
- ii. Generate random variables uniformly distributed over  $-\frac{q}{2}$  to  $\frac{q}{2}$ . For each quantization error value, calculate mean error, variance error, and average power (which is equivalent to noise power), and then use Noise Power obtained and Signal Power to calculate the SNR.
- iii. The number of bits required for quantization is calculated as  $1 - \log_2(q)$ .
- iv. Compare the calculated SNR to the target SNR\_dB, and when it's within a specified tolerance, print the corresponding number of bits required for quantization.

- v. The program breaks the loop and exits after finding the number of bits that achieves the target SNR<sub>dB</sub>.

## Chapter 6

# Random Algebra

1. Let  $(X, Y)$  have joint probability density function

$$p_{XY}(x, y) = \begin{cases} 8xy & \text{if } 0 < x < y < 1 \\ 0 & \text{otherwise} \end{cases} \quad (6.1)$$

if  $E(X|Y = y_0) = \frac{1}{2}$ , then  $y_0$  equals

- (a)  $\frac{3}{4}$
- (b)  $\frac{1}{2}$
- (c)  $\frac{1}{3}$
- (d)  $\frac{2}{3}$

(GATE ST 2023)

**Solution:**

$$E(X|Y) = \int_{-\infty}^{\infty} xp_{X|Y}dx \quad (6.2)$$

where

$$p_{X|Y} = \frac{p_{XY}(x, y)}{p_Y(y)} \quad (6.3)$$

$$p_Y(y) = \int_0^y p_{X|Y}(x, y) dx \quad (6.4)$$

for  $0 < y < 1$

$$= \int_0^y 8xy dx \quad (6.5)$$

$$= 8y \left[ \frac{x^2}{2} \right]_0^y \quad (6.6)$$

$$= 4y^3 \quad (6.7)$$

For  $0 < x < y < 1$ , on substituting  $p_Y(y)$  we get

$$p_{X|Y} = \frac{8xy}{4y^3} \quad (6.8)$$

$$= \frac{2x}{y^2} \quad (6.9)$$

and

$$E(X|Y = y_0) = \int_0^{y_0} x \cdot \frac{2x}{y_0^2} dx \quad (6.10)$$

$$= \frac{2}{y_0^2} \left[ \frac{x^3}{3} \right]_0^{y_0} \quad (6.11)$$

$$= \frac{2y_0}{3} \quad (6.12)$$

$$\Rightarrow \frac{2y_0}{3} = \frac{1}{2} \quad (6.13)$$

$$y_0 = \frac{3}{4} \quad (6.14)$$

## Chapter 7

# Hypothesis Testing

7.1 Suppose that  $x$  is an observed sample of size 1 from a population with probability density function  $f(\cdot)$ . Based on  $x$ , consider testing

$$H_0 : f(y) = \frac{1}{\sqrt{2\pi}} e^{-\frac{y^2}{2}}; \quad y \in \mathbb{R}$$

against

$$H_1 : f(y) = \frac{1}{2} e^{-|y|}; \quad y \in \mathbb{R}.$$

Then which one of the following statements is true?

- (a) The most powerful test rejects  $H_0$  if  $|x| > c$  for some  $c > 0$
- (b) The most powerful test rejects  $H_0$  if  $|x| < c$  for some  $c > 0$
- (c) The most powerful test rejects  $H_0$  if  $||x| - 1| > c$  for some  $c > 0$
- (d) The most powerful test rejects  $H_0$  if  $||x| - 1| < c$  for some  $c > 0$

(GATE ST 2023) **Solution:**

$$L = \prod_{i=1}^1 f(x) = f(x) \tag{7.1}$$

To determine the most powerful test, we need to consider the likelihood ratio test

$$\frac{L(H_1)}{L(H_0)} \underset{H_0}{\overset{H_1}{\geq}} k \quad (7.2)$$

$$\implies \frac{\frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}}}{\frac{1}{2} e^{-2|x|}} \underset{H_0}{\overset{H_1}{\geq}} k \quad (7.3)$$

$$\implies e^{\frac{x^2 - 2|x|}{2}} \underset{H_0}{\overset{H_1}{\geq}} k \frac{\sqrt{\pi}}{\sqrt{2}} \quad (7.4)$$

$$(|x| - 1)^2 \underset{H_0}{\overset{H_1}{\geq}} 2 \log \left( \frac{k\sqrt{\pi}}{\sqrt{2}} \right) + 1 \quad (7.5)$$

Taking square root on both sides,

$$||x| - 1| \underset{H_0}{\overset{H_1}{\geq}} \sqrt{2 \log \left( \frac{k\sqrt{\pi}}{\sqrt{2}} \right) + 1} \quad (7.6)$$

$$\implies |x| \underset{H_0}{\overset{H_1}{\geq}} 1 + \sqrt{2 \log \left( \frac{k\sqrt{\pi}}{\sqrt{2}} \right) + 1} \quad (7.7)$$

Hence, the correct answer is (7.1c)

7.2 Suppose that  $X_1, X_2, \dots, X_n$  are independent and identically distributed random variables, each having probability density function  $f(\cdot)$  and median  $\theta$ . We want to test  $H_0 : \theta = \theta_0$  against  $H_1 : \theta > \theta_0$

Consider a test that rejects  $H_0$  if  $S > c$  for some  $c$  depending on the size of the test, where  $S$  is the cardinality of the set  $\{i : X_i > \theta_0, 1 \leq i \leq n\}$ . Then which one of the following statements is true?

- (a) Under  $H_0$ , the distribution of  $S$  depends on  $f(\cdot)$ .
- (b) Under  $H_1$ , the distribution of  $S$  does not depend on  $f(\cdot)$ .
- (c) The power function depends on  $\theta$ .
- (d) The power function does not depend on  $\theta$ .

(GATE ST 2023)

**Solution:**

**Definition 7.1:** Median  $\theta$  is defined as

$$\Pr(X_i \leq \theta) = 0.5 \text{ for all } i \text{ from } 1 \text{ to } n.$$

**Definition 7.2:**  $S$  is defined as

$$S = \sum_{i=1}^n I(X_i > \theta_0)$$

where  $I(X_i > \theta_0)$  represents an indicator function.

$$I(X_i > \theta_0) = \begin{cases} 1, & \text{if } X_i > \theta_0 \\ 0, & \text{if } X_i \leq \theta_0 \end{cases} \quad (7.8)$$

$$E(S) = E\left(\sum_{i=1}^n I(X_i > \theta_0)\right) \quad (7.9)$$

$$= \sum_{i=1}^n E(I(X_i > \theta_0)) \quad (7.10)$$

Since,

$$E(I(X_i > \theta_0)) = P(X_i > \theta_0) = \int_{\theta_0}^{\infty} f(x) dx \quad (7.11)$$

Therefore,

$$E(S) = \sum_{i=1}^n \int_{\theta_0}^{\infty} f(x) dx \quad (7.12)$$

(a) From (6.12), under  $H_0$ , the distribution of  $S$  depends on  $f(\cdot)$ .

(b) The power function can be expressed as:

$$\pi(\theta) = \Pr(\text{Reject } H_0 \mid H_1 \text{ is true}) \quad (7.13)$$

$$= \Pr(S > c \mid \theta) \quad (7.14)$$

Therefore, power function depends on value of  $\theta$ .

7.3 Let  $X_1, X_2, X_3, \dots, X_n$  be a random sample of size  $n (\geq 2)$  from a population having probability density function

$$f(x; \theta) = \begin{cases} \frac{2}{\theta x} (\log_e x) e^{-\frac{(\log_e x)^2}{\theta}} & , 0 < x < 1 \\ 0 & , \text{otherwise} \end{cases}$$

where  $\theta > 0$  is an unknown parameter. Then which of the following statements is true,

- (A)  $\frac{1}{n} \sum_{i=1}^n (\ln X_i)^2$  is the maximum likelihood estimator of  $\theta$
- (B)  $\frac{1}{n-1} \sum_{i=1}^n (\ln X_i)^2$  is the maximum likelihood estimator of  $\theta$
- (C)  $\frac{1}{n} \sum_{i=1}^n \ln X_i$  is the maximum likelihood estimator of  $\theta$
- (D)  $\frac{1}{n-1} \sum_{i=1}^n \ln X_i$  is the maximum likelihood estimator of  $\theta$

(GATE ST 2023)

**Solution:**

$$L(\theta) = f(x_1, x_2, \dots, x_n; \theta) \quad (7.15)$$

The product of pdfs can be used to approximate the likelihood function even if the

variables are dependent. This is a general approach that is often used in practice to estimate MLE of  $\theta$ . Therefore,

$$L(\theta) = \prod_{i=1}^n f(x_i; \theta) \quad (7.16)$$

Maximizing  $L(\theta)$  is equivalent to maximizing the  $\ln L(\theta)$  as  $\ln$  is a monotonically increasing function.

$$l(\theta) = \ln L(\theta) \quad (7.17)$$

$$= \ln \left( \prod_{i=1}^n f(x_i; \theta) \right) \quad (7.18)$$

$$= \sum_{i=1}^n \ln f(x_i; \theta) \quad (7.19)$$

$$= -n \ln 2 - n \ln \theta + \sum_{i=1}^n \ln(-\ln x_i) - \sum_{i=1}^n (\ln x_i) - \sum_{i=1}^n \frac{(\ln x_i)^2}{\theta} \quad (7.20)$$

Maximizing  $l(\theta)$  with respect to  $\theta$  gives the MLE estimation, therefore

$$\frac{\partial l(\theta)}{\partial \theta} = 0 \quad (7.21)$$

$$\frac{-n}{\theta} + \frac{1}{(\theta)^2} \sum_{i=1}^n (\ln x_i)^2 = 0 \quad (7.22)$$

$$\theta = \frac{1}{n} \sum_{i=1}^n (\ln x_i)^2 \quad (7.23)$$

Hence (A) is the true statement.

7.4 Suppose that  $(X, Y)$  has joint probability mass function

$$P(X = 0, Y = 0) = P(X = 1, Y = 1) = \theta, \quad (7.24)$$

$$P(X = 1, Y = 0) = P(X = 0, Y = 1) = \frac{1}{2} - \theta. \quad (7.25)$$

where  $0 \leq \theta \leq \frac{1}{2}$  is an unknown parameter. Consider testing  $H_0 : \theta = \frac{1}{4}$  against  $H_1 : \theta = \frac{1}{3}$ ; based on a random sample  $(X_1, Y_1), (X_2, Y_2), \dots, (X_n, Y_n)$  from the above probability mass function. Let  $M$  be the cardinality of the set  $\{i : X_i = Y_i, 1 \leq i \leq n\}$ . If  $m$  is the observed value of  $M$ , then which one of the following statements is true?

- (a) The likelihood ratio test rejects  $H_0$  if  $m > c$  for some  $c$ .
- (b) The likelihood ratio test rejects  $H_0$  if  $m < c$  for some  $c$ .
- (c) The likelihood ratio test rejects  $H_0$  if  $c_1 < m < c_2$  for some  $c_1$  and  $c_2$ .
- (d) The likelihood ratio test rejects  $H_0$  if  $m < c_1$  or  $m > c_2$  for some  $c_1$  and  $c_2$ .

(GATE ST 2023)

**Solution:** Given that,

$$H_0 : \quad \theta = \theta_0 = \frac{1}{4}, \quad (7.26)$$

$$H_1 : \quad \theta = \theta_1 = \frac{1}{3}. \quad (7.27)$$

and the pmf is given by

$$p_{XY}(0, 0) = p_{XY}(1, 1) = \theta \quad (7.28)$$

$$p_{XY}(0, 1) = p_{XY}(1, 0) = \frac{1}{2} - \theta \quad (7.29)$$

Then for the given random sample of data,

$$p_{X_i, Y_i}(x, y) = \begin{cases} 2\theta & x = y \\ 1 - 2\theta & x \neq y \end{cases} \quad (7.30)$$

$$(7.31)$$

Then the likelihood of the data under  $H_0$  is given by:

$$L(\theta_0 \mid data) = \prod_{i=1}^n p_{X_i, Y_i}(x, y) \quad (7.32)$$

$$= (2\theta_0)^m (1 - 2\theta_0)^{n-m} \quad (7.33)$$

$$= \left(\frac{1}{2}\right)^m \left(\frac{1}{2}\right)^{n-m} \quad (7.34)$$

Then the likelihood of the data under  $H_1$  is given by:

$$L(\theta_1 \mid data) = \prod_{i=1}^n p_{X_i, Y_i}(x, y) \quad (7.35)$$

$$= (2\theta_1)^m (1 - 2\theta_1)^{n-m} \quad (7.36)$$

$$= \left(\frac{2}{3}\right)^m \left(\frac{1}{3}\right)^{n-m} \quad (7.37)$$

The likelihood ratio will be

$$\lambda(data) = \frac{L(\theta_1 \mid x)}{L(\theta_0 \mid x)} \quad (7.38)$$

$$= \frac{\left(\frac{2}{3}\right)^m \left(\frac{1}{3}\right)^{n-m}}{\left(\frac{1}{2}\right)^m \left(\frac{1}{2}\right)^{n-m}} = (2)^m \left(\frac{2}{3}\right)^n \quad (7.39)$$

Let the critical value be denoted by  $c_1$ , then the likelihood ratio test rejects  $H_0$  if

$$\implies \lambda(data) \underset{H_0}{\overset{H_1}{\geq}} c_1 \quad (7.40)$$

$$(7.41)$$

From (7.39),

$$\implies (2)^m \left(\frac{2}{3}\right)^n \underset{H_0}{\overset{H_1}{\geq}} c_1 \quad (7.42)$$

$$\implies (2)^m \underset{H_0}{\overset{H_1}{\geq}} c_1 \left(\frac{2}{3}\right)^n \quad (7.43)$$

$$\implies m \underset{H_0}{\overset{H_1}{\geq}} \log_2 \left( c_1 \left(\frac{2}{3}\right)^n \right) \quad (7.44)$$

$$\implies m \underset{H_0}{\overset{H_1}{\geq}} c \quad \exists c \in \mathbb{R} \quad (7.45)$$

where,

$$c = \log_2 \left( c_1 \left(\frac{2}{3}\right)^n \right) \quad (7.46)$$

$\therefore$  From (7.45), Option A is correct and Options B,C,D are incorrect

7.5 Let  $X$  be a random sample of size 1 from a population with cumulative distribution function

$$F_X(x) = \begin{cases} 0 & \text{if } x \leq 0 \\ 1 - (1 - x)^\theta & \text{if } 0 \leq x < 1 \\ 1 & \text{if } x \geq 1, \end{cases} \quad (7.47)$$

where  $\theta > 0$  is an unknown parameter. To test  $H_0 : \theta = 1$  against  $H_1 : \theta = 2$ , consider

using the critical region  $(x \in \mathbb{R} : x < 0.5)$ . If  $\alpha$  and  $\beta$  denote the level and power of the test, respectively, then  $\alpha + \beta$  (rounded off to two decimal places) equals (GATE ST 2023)

**Solution:** Given that,

$$H_0 : \theta = \theta_0 = 1 \quad (7.48)$$

$$H_1 : \theta = \theta_1 = 2 \quad (7.49)$$

PDF can be defined as:

$$p_X(x) = \frac{d}{dx} F_X(x) \quad (7.50)$$

$$= \begin{cases} \theta (1-x)^{\theta-1} & \text{if } 0 \leq x < 1 \\ 0 & \text{otherwise} \end{cases} \quad (7.51)$$

Level of test:

$$\alpha = \Pr(\text{reject } H_0 | H_0 \text{ is true}) \quad (7.52)$$

$$= \Pr(x < 0.5 | \theta_0) \quad (7.53)$$

$$= F_X(0.5) \quad (7.54)$$

$$= 1 - (1 - 0.5) \quad (7.55)$$

$$= \frac{1}{2} \quad (7.56)$$

Power of test:

$$\beta = \Pr(\text{reject } H_0 | H_1 \text{ is true}) \quad (7.57)$$

$$= \Pr(x < 0.5 | \theta_1) \quad (7.58)$$

$$= F_X(0.5) \quad (7.59)$$

$$= 1 - (1 - 0.5)^2 \quad (7.60)$$

$$= \frac{3}{4} \quad (7.61)$$

Now,

$$\alpha + \beta = \frac{1}{2} + \frac{3}{4} \quad (7.62)$$

$$= 1.25 \quad (7.63)$$

7.6 Using the Ordinary Least Squares (OLS) method, a researcher estimated the relationship between initial salary (S) of MBA graduates and their cumulative grade point average (CGPA) as

$$\hat{S}_i = \hat{\beta}_0 + \hat{\beta}_1 \text{CGPA}_i, i = 1, 2, \dots, 100$$

where  $\hat{\beta}_0 = 4543$  and  $\hat{\beta}_1 = 645.08$ . The standard errors of  $\hat{\beta}_0$  and  $\hat{\beta}_1$  are 921.79 and 70.01, respectively.

The t-statistic for testing the null hypothesis  $\beta_1 = 0$  is (GATE XH 2023)

**Solution:**

**Definition 7.3(*t-statistic*):** The t-statistic is the ratio of the difference between

the estimated value of a parameter from its hypothesized value to its standard error.

$$t_{\hat{\beta}_1} = \frac{\hat{\beta}_1 - \beta_1}{SE(\hat{\beta}_1)} \quad (7.64)$$

where,

- $\hat{\beta}_1$  is the point estimate.
- $\beta_1$  is the hypothesized value.
- $SE(\hat{\beta}_1)$  standard error of the estimator.

**Definition 7.4(Standard error):** It is a measure of how much the statistic is likely to vary from the true value of the parameter it is estimating.

$$SE(\hat{\beta}_1) = \sqrt{\frac{s^2}{n-2}} \quad (7.65)$$

where,

- $s^2$  is the variance
- $n$  is the sample size

Given that  $\hat{\beta}_1 = 645.08$  and  $SE(\hat{\beta}_1) = 70.01$ , we get

$$t_{\hat{\beta}_1} = \frac{645.08 - 0}{70.01} \quad (7.66)$$

$$t_{\hat{\beta}_1} = 9.21 \quad (7.67)$$

7.7 Let  $\{0.13, 0.12, 0.78, 0.51\}$  be a realization of a random sample of size 4 from a

population with cumulative distribution function  $F(\cdot)$ . Consider testing

$$H_0 : F = F_0 \quad \text{against} \quad H_1 : F \neq F_0 \quad (7.68)$$

where,

$$F_0(x) = \begin{cases} 0 & x < 0 \\ x & 0 \leq x < 1 \\ 1 & x \geq 1 \end{cases} \quad (7.69)$$

Let  $D$  denote the Kolmogorov-Smirnov test statistic. If  $P(D > 0.669) = 0.01$  under  $H_0$  and

$$\psi = \begin{cases} 1 & \text{if } H_0 \text{ is accepted at level } 0.01 \\ 0 & \text{otherwise} \end{cases} \quad (7.70)$$

then based on the given data, the observed value of  $D + \psi$  (rounded off to two decimal places) equals (GATE ST 2023)

**Solution:** Its given that random sample is of size 4, So

$$n = 4 \quad (7.71)$$

The cdf of the random sample is given as

$$F_X(x) = \begin{cases} 0 & x < 0 \\ x & 0 \leq x < 1 \\ 1 & x \geq 1 \end{cases} \quad (7.72)$$

The empirical distribution function(edf)  $G_n$  for  $n$  independent and identically distributed (i.i.d.) ordered observations  $X_i$  is defined as

$$G_n(x) = \frac{\text{no of (elements in the sample } \leq x)}{n} = \frac{1}{n} \sum_{i=1}^n 1(X_i \leq x) \quad (7.73)$$

where  $1(A)$  is the indicator of event  $A$  and in (7.73) it is defined as,

$$1(X_i \leq x) = \begin{cases} 1 & X_i \leq x \\ 0 & \text{otherwise} \end{cases} \quad (7.74)$$

From (7.71), (7.72) and (7.73), the edf for the given data will be

$$G_n(0.13) = \frac{1}{4} \sum_{i=1}^n 1(X_i \leq 0.13) = \frac{1}{2} \quad (7.75)$$

$$G_n(0.12) = \frac{1}{4} \sum_{i=1}^n 1(X_i \leq 0.12) = \frac{1}{4} \quad (7.76)$$

$$G_n(0.78) = \frac{1}{4} \sum_{i=1}^n 1(X_i \leq 0.78) = 1 \quad (7.77)$$

$$G_n(0.51) = \frac{1}{4} \sum_{i=1}^n 1(X_i \leq 0.51) = \frac{3}{4} \quad (7.78)$$

The Kolmogorov–Smirnov statistic for a given cdf  $F_X(x)$  is

$$D_n = \sup |G_n(x) - F_X(x)| \quad (7.79)$$

The difference between cdf and edf for the given data will be (i.e.,  $\forall x \in \{0.13, 0.12, 0.78, 0.51\}$ )

$$G_n(0.13) - F_X(0.13) = 0.37 \quad (7.80)$$

$$G_n(0.12) - F_X(0.12) = 0.25 \quad (7.81)$$

$$G_n(0.78) - F_X(0.78) = 0.22 \quad (7.82)$$

$$G_n(0.51) - F_X(0.51) = 0.24 \quad (7.83)$$

Then

$$D_n = \sup(0.37, 0.25, 0.22, 0.24) = 0.37 \quad (7.84)$$

Given that,

$$P(D > 0.669) = 0.01 \quad (7.85)$$

Then

$$H_0 = \begin{cases} \text{accepted at level 0.01} & \text{if } D_n \leq 0.669 \\ \text{rejected at level 0.01} & \text{if } D_n > 0.669 \end{cases} \quad (7.86)$$

From (7.84) and (7.86); We can say that  $H_0$  is accepted at level 0.01 and

$$\psi = 1 \quad (7.87)$$

$\therefore$  the value will be

$$\psi + D_n = 1 + 0.37 = 1.37 \quad (7.88)$$

## Chapter 8

# Bivariate Random Variables

## Chapter 9

# Random Processes

9.1 Let  $X(t)$  be a Gaussian noise with power spectral density  $\frac{1}{2}W/Hz$ . If  $X(t)$  is input to an LTI system with impulse response  $e^{-tu(t)}$ . The average power of the system is (rounded off to two decimal places). (GATE EC 2023)

**Solution:** The output power spectral density of a LTI system with impulse response  $h(t)$  and input  $X(t)$  and input power spectral density  $S_X(f)$  is given by:

$$S_Y(f) = |H(f)|^2 S_X(f) \quad (9.1)$$

where  $H(f)$  is frequency response of the system.

$H(f)$  can be found by taking fourier transform of  $h(t)$

$$H(f) \xleftrightarrow{\mathcal{F}} \frac{1}{j2\pi f + 1} \quad (9.2)$$

The average power of a signal with power spectral density  $S(f)$  is given by:

$$P_Y(f) = \int_{-\infty}^{\infty} S_Y(f) df \quad (9.3)$$

Substituting  $S_Y(f)$  in the equation we get:

$$P_Y(f) = \int_{-\infty}^{\infty} |H(f)|^2 \cdot S_X(f) df \quad (9.4)$$

$$= \int_{-\infty}^{\infty} \left| \frac{1}{j2\pi f + 1} \right|^2 \cdot \frac{1}{2} df \quad (9.5)$$

$$= \frac{1}{2} \int_{-\infty}^{\infty} \frac{1}{(2\pi f)^2 + 1} df \quad (9.6)$$

$$= \frac{1}{2} \times 2 \int_0^{\infty} \frac{1}{(2\pi f)^2 + (1)^2} df \quad (9.7)$$

$$= \int_0^{\infty} \frac{1}{(2\pi f)^2 + (1)^2} df \quad (9.8)$$

$$= \frac{1}{2\pi} \tan^{-1}(x) \Big|_0^{\infty} \quad (9.9)$$

$$= \frac{1}{2\pi} (\tan^{-1} \infty - \tan^{-1} 0) \quad (9.10)$$

$$= \frac{1}{2\pi} \left( \frac{\pi}{2} - 0 \right) \quad (9.11)$$

$$= \frac{1}{2\pi} \left( \frac{\pi}{2} \right) \quad (9.12)$$

$$= \frac{1}{4} \quad (9.13)$$

Rounded off to two decimal places, the average power of the system output is  $0.25W$ .

# Chapter 10

## Convergence

10.1 Let  $\{X_n\}_{n \geq 1}$  and  $\{Y_n\}_{n \geq 1}$  be two sequences of random variables and  $X$  and  $Y$  be two random variables, all of them defined on the same probability space. Which one of the following statements is true?

- (A) If  $\{X_n\}_{n \geq 1}$  converges in distribution to a real constant  $c$ , then  $\{X_n\}_{n \geq 1}$  converges in probability to  $c$ .
- (B) If  $\{X_n\}_{n \geq 1}$  converges in probability to  $X$ , then  $\{X_n\}_{n \geq 1}$  converges in  $3^{rd}$  mean to  $X$ .
- (C) If  $\{X_n\}_{n \geq 1}$  converges in distribution to  $X$  and  $\{Y_n\}_{n \geq 1}$  converges in distribution to  $Y$ , then  $\{X_n + Y_n\}_{n \geq 1}$  converges in distribution to  $X + Y$ .
- (D) If  $\{E(X_n)\}_{n \geq 1}$  converges to  $E(X)$ , then  $\{X_n\}_{n \geq 1}$  converges in  $1^{st}$  mean to  $X$ .

(GATE ST 2023) **Solution:**

- (a)  $X_n$  converges in distribution to  $X$ ,  $X_n \xrightarrow{d} X$ , then for all  $x$ ,

$$\lim_{n \rightarrow \infty} F_{X_n}(x) = F_X(x) \quad (10.1)$$

- (b)  $X_n$  converges in probability to  $X$ ,  $X_n \xrightarrow{p} X$ , then for all  $\epsilon > 0$ ,

$$\lim_{n \rightarrow \infty} \Pr(|X_n - X| > \epsilon) = 0 \quad (10.2)$$

(c)  $X_n$  converges in  $p^{th}$  mean to  $X$ , then we have

$$\lim_{n \rightarrow \infty} E(|X_n - X|^p) = 0 \quad (10.3)$$

(A) For  $\epsilon > 0$ ,  $B$  be defined as

$$B = \{x : |x - c| \geq \epsilon\} \quad (10.4)$$

Now,

$$\Pr(|X_n - c| \geq \epsilon) = \Pr(X_n \in B) \quad (10.5)$$

Using Portmanteau Lemma, if  $X_n \xrightarrow{d} c$ , we have

$$\limsup_{n \rightarrow \infty} \Pr(X_n \in B) \leq \Pr(c \in B) \quad (10.6)$$

$$\leq \Pr(|0 - 0| \geq \epsilon) \quad (10.7)$$

$$\leq \Pr(0 \geq \epsilon) \quad (10.8)$$

$$\leq 0 \quad (10.9)$$

$$= 0 \quad (10.10)$$

$$\lim_{n \rightarrow \infty} \Pr(|X_n - c| > \epsilon) = 0 \quad (10.11)$$

From (10.2),  $X_n \xrightarrow{p} c$ . So, we have

$$X_n \xrightarrow{d} c \implies X_n \xrightarrow{p} c \quad (10.12)$$

Option (A) is correct.

(B) Statement (B) is may or may not correct. Counter Example: Consider distribution

$X_n$	0	$n$
$\Pr(X_n)$	$1 - \frac{1}{n}$	$\frac{1}{n}$

For  $\epsilon > 0$ ,  $X_n$  converges in probability to  $X = 0$

$$\lim_{n \rightarrow \infty} \Pr(|X_n - X| > \epsilon) = \lim_{n \rightarrow \infty} \Pr(X_n > \epsilon) \quad (10.13)$$

$X_n > \epsilon$  is subset of  $X_n = n$  since every time  $X_n$  equals  $n$ , it's also true that  $X_n$  is greater than  $\epsilon$ . But there may be times when  $X_n$  is greater than  $\epsilon$  without  $X_n$  being equal to  $n$ . So,

$$\Pr(X_n > \epsilon) \leq \Pr(X_n = n) \quad (10.14)$$

$$\lim_{n \rightarrow \infty} \Pr(|X_n - X| > \epsilon) \leq \lim_{n \rightarrow \infty} \Pr(X_n = n) \quad (10.15)$$

$$\leq \lim_{n \rightarrow \infty} \frac{1}{n} \quad (10.16)$$

$$\leq 0 \quad (10.17)$$

$$= 0 \quad (10.18)$$

But  $X_n$  does not converges in  $3^{rd}$  mean to  $X = 0$ .

$$\lim_{n \rightarrow \infty} E(|X_n - X|^3) = \lim_{n \rightarrow \infty} E(X_n^3) \quad (10.19)$$

$$= \lim_{n \rightarrow \infty} 0^3 \left(1 - \frac{1}{n}\right) + n^3 \left(\frac{1}{n}\right) \quad (10.20)$$

$$= \lim_{n \rightarrow \infty} n^2 \neq 0 \quad (10.21)$$

(C) Statement (C) is may or may not correct. Counter Example: Consider distribution

$$Z \sim \mathcal{N}(0, 1) \quad (10.22)$$

Let  $\{X_n\}_{n \geq 1}$  and  $\{Y_n\}_{n \geq 1}$  be sequences of random variables such that they both converge in distribution as  $Z$  and  $(-1)^n Z$ . Proof that  $Y_n$  converges in distribution.

For  $n$  even

$$\lim_{n \rightarrow \infty} F_{Y_n}(x) = \Pr(Z \leq x) \quad (10.23)$$

For  $n$  odd

$$\lim_{n \rightarrow \infty} F_{Y_n}(x) = \Pr(-Z \leq x) \quad (10.24)$$

$$= \Pr(Z \leq x) \quad (10.25)$$

Proved. So, we have

$$F_{X_n+Y_n}(x) = \Pr(X_n + Y_n \leq x) \quad (10.26)$$

$$= \Pr(Z + (-1)^n Z \leq x) \quad (10.27)$$

For  $n$  is even

$$F_{X_n+Y_n}(x) = \Pr(2Z \leq x) \quad (10.28)$$

$$= \Pr\left(Z \leq \frac{x}{2}\right) \quad (10.29)$$

$$= 1 - \Pr\left(Z > \frac{x}{2}\right) \quad (10.30)$$

$$\approx 1 - Q\left(\frac{x}{2}\right) \quad (10.31)$$

For  $n$  is odd

$$F_{X_n+Y_n}(x) = \Pr(0 \leq x) \quad (10.32)$$

$$= \begin{cases} 1 & \text{if } x \geq 0 \\ 0 & \text{if } x < 0 \end{cases} = H(x) \quad (10.33)$$

So, on generalizing

$$F_{X_n+Y_n}(x) = \begin{cases} 1 - Q\left(\frac{x}{2}\right) & \text{if } n \text{ is even} \\ H(x) & \text{if } n \text{ is odd} \end{cases} \quad (10.34)$$

$\lim_{n \rightarrow \infty} F_{X_n+Y_n}(x)$  oscillate between  $1 - Q\left(\frac{x}{2}\right)$  and  $H(x)$ . This doesnot imply convergence.

(D) Statement (D) is may or may not correct. Counter Example: Consider

$X_n$	0	$n$
$\Pr(X_n)$	$1 - \frac{1}{n}$	$\frac{1}{n}$

$$\lim_{n \rightarrow \infty} E(X_n) = 0 \left(1 - \frac{1}{n}\right) + n \left(\frac{1}{n}\right) \quad (10.35)$$

$$= 1 \quad (10.36)$$

As  $n \rightarrow \infty$ ,  $E(X_n)$  converges to  $E(X) = 1$ .

$$\lim_{n \rightarrow \infty} X_n = 0 = X \quad (10.37)$$

To find 1<sup>st</sup> mean convergence of  $X_n$ . From (10.36)

$$\lim_{n \rightarrow \infty} E(|X_n - X|) = \lim_{n \rightarrow \infty} E(X_n) \quad (10.38)$$

$$= 1 \neq 0 \quad (10.39)$$

So,  $X_n$  does not converge in 1<sup>st</sup> mean to  $X$ .

10.2 Let  $\{X_n\}_{n \geq 1}$  be a sequence of independent and identically distributed random variables each having a mean 4 and variance 9. If  $Y_n = \frac{1}{n} \sum_{i=1}^n X_i$  for  $n \geq 1$ , then  $\lim_{n \rightarrow \infty} E \left[ \left( \frac{Y_n - 4}{\sqrt{n}} \right)^2 \right]$  (in integer) equals \_\_\_\_\_. (GATE ST 2023)

**Solution:**

(a) **Theory:** For all  $X_i$  which are i.i.d's, mean  $\mu = 4$  and variance  $\sigma^2 = 9$ ,

$$Y_n = \frac{1}{n} \sum_{i=1}^n X_i \quad (10.40)$$

The mean of a sum of i.i.d random variables is calculated as

$$E[Y_n] = E \left[ \frac{1}{n} \sum_{i=1}^n X_i \right] \quad (10.41)$$

$$= \frac{1}{n} \sum_{i=1}^n E[X_i] \quad (10.42)$$

$$= \frac{1}{n} (n\mu) \quad (10.43)$$

$$= \mu \quad (10.44)$$

The variance of a sum of i.i.d random variables is calculated as

$$\text{var}(Y_n) = \text{E} \left[ \left( \frac{1}{n} \sum_{i=1}^n X_i \right)^2 \right] - \left( \text{E} \left[ \frac{1}{n} \sum_{i=1}^n X_i \right] \right)^2 \quad (10.45)$$

$$= \frac{1}{n^2} \left\{ \text{E} \left[ \left( \sum_{i=1}^n X_i \right)^2 \right] - \left( \text{E} \left[ \sum_{i=1}^n X_i \right] \right)^2 \right\} \quad (10.46)$$

But

$$\text{E} \left[ \left( \sum_{i=1}^n X_i \right)^2 \right] = \text{E} \left[ \sum_{i=1}^n \sum_{j=1}^n X_i X_j \right] \quad (10.47)$$

$$= \sum_{i=1}^n \sum_{j=1}^n \text{E} [X_i X_j] \quad (10.48)$$

and

$$\left( \text{E} \left[ \sum_{i=1}^n X_i \right] \right)^2 = \left( \sum_{i=1}^n \text{E} [X_i] \right)^2 \quad (10.49)$$

$$= \sum_{i=1}^n \sum_{j=1}^n \text{E} [X_i] \text{E} [X_j] \quad (10.50)$$

Putting (10.48) and (10.50) in (10.46), and using the definition of covariance,

$$\text{var}(Y_n) = \frac{1}{n^2} \left\{ \sum_{i=1}^n \sum_{j=1}^n (\text{E} [X_i X_j] - \text{E} [X_i] \text{E} [X_j]) \right\} \quad (10.51)$$

$$= \frac{1}{n^2} \left\{ \sum_{i=1}^n \sum_{j=1}^n \text{cov}(X_i, X_j) \right\} \quad (10.52)$$

As all the variables are i.i.d's and are thus uncorrelated,

$$\text{cov}(X_i, X_j) = \begin{cases} 0 & \text{if } i \neq j \\ \text{var}(X_i) & \text{if } i = j \end{cases} \quad (10.53)$$

Putting (10.53) in (10.52),

$$\text{var}(Y_n) = \frac{1}{n^2} \left( \sum_{i=1}^n \text{cov}(X_i, X_i) \right) \quad (10.54)$$

$$= \frac{1}{n^2} \left( \sum_{i=1}^n \text{var}(X_i) \right) \quad (10.55)$$

$$= \frac{1}{n^2} \left( \sum_{i=1}^n \sigma^2 \right) \quad (10.56)$$

$$= \frac{\sigma^2}{n} \quad (10.57)$$

Consider the term  $\left( \frac{Y_n - \mu}{\sqrt{n}} \right)^2$ . Calculating its expectation,

$$\text{E} \left[ \left( \frac{Y_n - \mu}{\sqrt{n}} \right)^2 \right] = \frac{1}{n} \text{E} [(Y_n - \mu)^2] \quad (10.58)$$

$$= \frac{1}{n} \text{var}(Y_n) \quad (10.59)$$

$$= \frac{\sigma^2}{n^2} \quad (10.60)$$

Substituting  $\sigma^2 = 9$  and  $\mu = 4$ , we get

$$\lim_{n \rightarrow \infty} \text{E} \left[ \left( \frac{Y_n - 4}{\sqrt{n}} \right)^2 \right] = \lim_{n \rightarrow \infty} \frac{9}{n^2} = 0 \quad (10.61)$$

(b) **Simulation:** Any distribution with mean  $\mu = 4$  and variance  $\sigma^2 = 9$  can be used for the variable  $X_{ij}$  for all  $i, j \in \mathbb{N}$ ; as shown in the Theory part, the limit is always

zero regardless of the distribution. The most straightforward distribution that can be used for  $X_{ij}$  is:

$$p_{X_{ij}}(x) = \begin{cases} 0.5 & \text{if } x \in \{1, 7\} \\ 0 & \text{otherwise} \end{cases} \quad (10.62)$$

This distribution has the following characteristics:

$$\mu = E[X_{ij}] = 0.5 \times 1 + 0.5 \times 7 = 4 \quad (10.63)$$

$$\sigma^2 = E[X_{ij}^2] - (E[X_{ij}])^2 \quad (10.64)$$

$$= (0.5 \times 1^2 + 0.5 \times 7^2) - 4^2 \quad (10.65)$$

$$= 9 \quad (10.66)$$

A matrix  $X_{n \times m}$  is generated for all  $i \leq n$  and  $j \leq m$ . Using this matrix, a set of  $m$  values for  $Y_j$  is generated as

$$Y_j = \frac{1}{n} \sum_{i=1}^n X_{ij} \quad (10.67)$$

Now, the expression  $\frac{(Y_j-4)^2}{n}$  is calculated for all  $j \leq m$  and their expectancy is calculated as follows:

$$E \left[ \left( \frac{Y_n - 4}{\sqrt{n}} \right)^2 \right] = \frac{1}{m} \sum_{j=1}^m \frac{(Y_j - 4)^2}{n} \quad (10.68)$$

To calculate the limit  $n \rightarrow \infty$ , different values of  $n$  are taken, and the expected value is calculated (taking a fixed small value of  $m$  to reduce computational time) for each case. This output is plotted and is seen to be close to the curve  $\frac{9}{n^2}$ , as

derived in (10.61). In both cases, we can observe the limit tends towards zero.

Figure 10.1: Expectation vs n

## Chapter 11

# Information Theory

1. The frequency of occurrence of 8 symbols (a-h) is shown in the table below. A symbol is chosen and it is determined by asking a series of “yes/no” questions which are assumed to be truthfully answered. The average number of questions when asked in the most efficient sequence, to determine the chosen symbol, is

Symbols	Frequency of occurrence
a	$\frac{1}{2}$
b	$\frac{1}{4}$
c	$\frac{1}{8}$
d	$\frac{1}{16}$
e	$\frac{1}{32}$
f	$\frac{1}{64}$
g	$\frac{1}{128}$
h	$\frac{1}{128}$

**Solution:**

Parameter	Value	Description
$X$	$1 \leq X \leq 8$	number of symbols
$l$	2	base of algorithm
$H(X)$	$\sum_i p_X(i) \log_l \left( \frac{1}{p_X(i)} \right)$	average number of question

$$H(X) = \sum_i p_X(i) \log_b \left( \frac{1}{p_X(i)} \right) \quad (11.1)$$

$$= \frac{1}{2} \log_2 (2) + \frac{1}{4} \log_2 (4) + \dots + \frac{1}{128} \log_2 (128) \quad (11.2)$$

$$= 0.5 + 0.5 + 0.375 + \dots + 0.0078125 \quad (11.3)$$

$$= 1.984375 \quad (11.4)$$

Now, finding the average using Huffman code, We start from a frequency of 1 and distribute it uniformly. The following conventions is used,

symbol	alloted bit
occured	1
not occured	0

Using the above binary table following code is generated;

Symbols	Frequency	Code	Size
$a$	$\frac{1}{2}$	1	0.5
$b$	$\frac{1}{4}$	01	0.25
$c$	$\frac{1}{8}$	001	0.125
$d$	$\frac{1}{16}$	0001	0.0625
$e$	$\frac{1}{32}$	00001	0.03125
$f$	$\frac{1}{64}$	000001	0.015625
$g$	$\frac{1}{128}$	0000001	0.0078125
$h$	$\frac{1}{128}$	0000000	0.0078125

Table 11.1: Huffman table

The average number of question = Weighted path length = 1.9844

2. The transition diagram of a discrete memoryless channel with three input symbols and three output symbols is shown in the figure. The transition probabilities are as marked.

The parameter  $\alpha$  lies in the interval  $[0.25, 1]$ . The value of  $\alpha$  for which the capacity of this channel is maximized, is (GATE EC 2022) **Solution:**

Variable	Description	Value
$x_i$	Input	$x_0, x_1, x_2$
$y_i$	Output	$y_0, y_1, y_2$
$p_i$	Input probability	$p_0, p_1, p_2$
$q_i$	Output probability	$q_0, q_1, q_2$
$C$	Channel Capacity	$C$
$I$	Mutual Information	$I$
$H$	Entropy	$H$

$$C = \sup_{p_X(x)} I(X, Y) \quad (11.5)$$

$$I(X, Y) = \sum_{x,y} p(x, y) \log_2 \frac{p(x, y)}{p(x) p(y)} \quad (11.6)$$

$$= \sum_{x,y} p(x, y) \log_2 \frac{p(y|x)}{p(y)} \quad (11.7)$$

$$= - \sum_{x,y} p(x, y) \log_2 p(y) + \sum_{x,y} p(x, y) \log_2 p(y|x) \quad (11.8)$$

$$= - \sum_y p(y) \log_2 p(y) - \left( - \sum_{x,y} p(x, y) \log_2 p(y|x) \right) \quad (11.9)$$

$$= H(Y) - H(Y|X) \quad (11.10)$$

Now,

$$\sum_{i=0}^2 p_i = 1 \quad (11.11)$$

$$\sum_{j=0}^2 q_j = 1 \quad (11.12)$$

$$H(\mathbf{q}) = - \sum_{i=0}^2 q_i \log_2 q_i \quad (11.13)$$

$$= - (q_0 \log_2 q_0 + q_1 \log_2 q_1 + q_2 \log_2 q_2) \quad (11.14)$$

$$H(Y|X) = - \sum_{i=0}^2 \sum_{j=0}^2 p_i p_{Y|X}(y_j|x_i) \log_2 (p_{Y|X}(y_j|x_i)) \quad (11.15)$$

$$\begin{aligned} &= -p_0((1-\alpha) \log_2(1-\alpha) + \alpha \log_2 \alpha) \\ &\quad - p_1((1-\alpha) \log_2(1-\alpha) + \alpha \log_2 \alpha) \\ &\quad - p_2((1-\alpha) \log_2(1-\alpha) + \alpha \log_2 \alpha) \end{aligned} \quad (11.16)$$

Using (11.14) and (11.16) in (11.10)

$$\begin{aligned} I(X, Y) &= - (q_0 \log_2 q_0 + q_1 \log_2 q_1 + q_2 \log_2 q_2) \\ &\quad + p_0((1-\alpha) \log_2(1-\alpha) + \alpha \log_2 \alpha) \\ &\quad + p_1((1-\alpha) \log_2(1-\alpha) + \alpha \log_2 \alpha) \\ &\quad + p_2((1-\alpha) \log_2(1-\alpha) + \alpha \log_2 \alpha) \end{aligned} \quad (11.17)$$

$$\Rightarrow \frac{d}{d\alpha} I(X, Y) = p_0 \log_2 \left( \frac{\alpha}{1-\alpha} \right) + p_1 \log_2 \left( \frac{\alpha}{1-\alpha} \right) + p_2 \log_2 \left( \frac{\alpha}{1-\alpha} \right) \quad (11.18)$$

For Maxima or minima  $\frac{d}{d\alpha} I(X, Y) = 0$

$$\log_2 \left( \frac{\alpha}{1-\alpha} \right) (p_0 + p_1 + p_2) = 0 \quad (11.19)$$

$$\Rightarrow \alpha = \frac{1}{2} \quad (11.20)$$

3. let  $H(X)$  denote the entropy of a discrete random variable  $X$  taking  $K$  possible distinct real values. Which of the following statements is/are necessarily true?

(A)  $H(X) \leq \log_2 K$  bits

(B)  $H(X) \leq H(2X)$

(C)  $H(X) \leq H(X^2)$

(D)  $H(X) \leq H(2^X)$

**Solution:**

Random independent variable	value of R.V	Description
$X$	$X \in (x_1, x_2, \dots, x_K)$	Value of the discrete variable $X$

(a) For Option(A) we will find

We know that :

$$\begin{aligned} \max_{p_X(k)} \quad & H(X) \\ \text{s.t.} \quad & \sum_{k=0}^K p_X(k) = 1 \end{aligned}$$

$\Rightarrow$

$$\begin{aligned} \max_{p_X(k)} \quad & - \sum_{k=0}^K p_X(k) \log_2 p_X(k) \\ \text{s.t.} \quad & \sum_{k=0}^K p_X(k) = 1 \end{aligned}$$

Now, we use lagranges multiplier to find the maximum entropy subject to the lagranges multiplier constant  $\lambda$  and  $p_X(k)$

$$L(p_X(k), \lambda) = - \sum_{k=0}^K p_X(k) \log_2 p_X(k) + \lambda \left( \sum_{k=0}^K p_X(k) - 1 \right) \quad (11.21)$$

$$\frac{\partial L}{\partial p_X(k)} = -\log_2 p_X(k) - 1 + \lambda \quad (11.22)$$

Now, we take the derivative of L with respect to each  $p_X(k)$  equal to zero for  $H(X)_{max}$

$$\lambda = \log_2 \frac{2}{k} \quad (11.23)$$

$$p_X(k) = 1/K \quad (11.24)$$

On solving, we get the value of

$$H(X)_{max} = \log_2 K \quad (11.25)$$

$$H(X) \leq \log_2 K \quad (11.26)$$

Hence, Option(A) is correct

(b) Let's consider the discrete variable as follows

$X \in x_i$	$p_X(k)$
-1	$\frac{1}{4}$
0	$\frac{1}{2}$
1	$\frac{1}{4}$

$$H(X) = \frac{1}{4} \log_2 4 + \frac{1}{2} \log_2 2 + \frac{1}{4} \log_2 4 \quad (11.27)$$

$$H(X) = 1.5 \text{ units} \quad (11.28)$$

Now  $Y = 2X$

$Y \in y_i$	$p_Y(k)$
-2	$\frac{1}{4}$
0	$\frac{1}{2}$
2	$\frac{1}{4}$

$$H(Y) = \sum_{i=0}^2 p_Y(k) \log_2 \frac{1}{p_Y(k)} \quad (11.29)$$

$$H(Y) = 1.5 \text{ units} \quad (11.30)$$

$$H(Y) = H(2X) = H(X) \quad (11.31)$$

Hence, Option(B) is correct

(c) Similarly on substituting  $Y = X^2$

$Y \in y_i$	$p_Y(k)$
0	$\frac{1}{2}$
1	$\frac{1}{2}$

$$H(Y) = \sum_{i=0}^1 p_Y(k) \log_2 \frac{1}{p_Y(k)} \quad (11.32)$$

$$H(Y) = 1 \text{ units} \quad (11.33)$$

$$H(Y) = H(X^2) \leq H(X) \quad (11.34)$$

Hence, Option(C) is incorrect

(d) Now for  $Y = 2^X$

$Y \in y_i$	$p_Y(k)$
$2^{-1} = \frac{1}{2}$	$\frac{1}{4}$
$2^0 = 1$	$\frac{1}{2}$
$2^1 = 2$	$\frac{1}{4}$

$$H(Y) = \sum_{i=0}^2 p_Y(k) \log_2 \frac{1}{p_Y(k)} \quad (11.35)$$

$$H(Y) = 1.5 \text{ units} \quad (11.36)$$

$$H(Y) = H(2^X) = H(X) \quad (11.37)$$

Hence, Option(D) is correct

The ans is (A), (B), (D)

These options are correct for the particular example.

## Chapter 12

# Markov chain

12.1 Let  $X_{n \geq 1}$  be a Markov chain with state space  $\{ 1, 2, 3 \}$  and transition probability matrix

$$\begin{pmatrix} \frac{1}{2} & \frac{1}{4} & \frac{1}{4} \\ \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \\ 0 & \frac{1}{2} & \frac{1}{2} \end{pmatrix}$$

Then  $\Pr(X_2 = 1 | X_1 = 1, X_3 = 2)$  equals

(GATE ST 2023)

**Solution:** Consider transition matrix as:

$$\begin{pmatrix} p_{11} & p_{12} & p_{13} \\ p_{21} & p_{22} & p_{23} \\ p_{31} & p_{32} & p_{33} \end{pmatrix} \quad (12.1)$$

$$\Pr(X_2 = 1 | X_1 = 1, X_3 = 2) = \Pr(X_2 = 1 | X_1 = 1) \quad (12.2)$$

$$= p_{11} \quad (12.3)$$

$$= 0.5 \quad (12.4)$$

(by markov's property and using transition probability matrix)

Figure 12.1: Markov Chain diagram

# Chapter 13

## Estimation

13.1 Let  $\{-1, -\frac{1}{2}, 1, \frac{5}{2}, 3\}$  be a realization of a random sample of size 5 from a population having  $N(\frac{1}{2}, \sigma^2)$  distribution, where  $\sigma > 0$  is an unknown parameter. Let  $T$  be an unbiased estimator of  $\sigma^2$  whose variance attains the Cramer-Rao lower bound. Then, based on the above data, the realized value of  $T$  (rounded off to two decimal places) equals (GATE ST 2023)

**Definition 13.1:** Unbiased Estimator is defined as

$$E(\hat{\sigma}^2) = \sigma^2 \quad (13.1)$$

where,  $E(\hat{\sigma}^2)$  represents the expected value of the estimator  $\hat{\sigma}^2$  and  $\sigma^2$  represents the true parameter

**Definition 13.2:** The Cramér-Rao bound can be defined as follows:

$$\text{Var}(\sigma^2) \geq \frac{1}{I(\sigma^2)} \quad (13.2)$$

where  $I(\sigma^2)$  represents fisher information for the parameter  $\sigma^2$ . Mathematically,

$$I(\sigma^2) = -E \left[ \frac{\partial^2}{\partial(\sigma)^2} \log P_X(X|\sigma^2) \right]$$

where,  $E[\cdot]$  represents the expected value and  $P_X(X|\sigma^2)$  is the p.d.f of random variable  $X$  given the parameter  $\sigma^2$ .

$P_X(X|\sigma^2)$  is given by:

$$P_X(X|\sigma^2) = \frac{1}{2\pi\sigma^2} \exp\left(-\frac{(X - \frac{1}{2})^2}{2\sigma^2}\right) \quad (13.3)$$

$$\log p_X(X|\sigma^2) = \log\left(\frac{1}{2\pi\sigma^2} \exp\left(-\frac{(X - \frac{1}{2})^2}{2\sigma^2}\right)\right) \quad (13.4)$$

$$= -\frac{1}{2} \log(2\pi\sigma^2) - \frac{(X - \frac{1}{2})^2}{2\sigma^2} \quad (13.5)$$

$$\frac{\partial^2}{\partial(\sigma^2)^2} \log P_X(X|\sigma^2) = \frac{1}{2\pi\sigma^2} - \frac{3(X - \frac{1}{2})^2}{\sigma^4} \quad (13.6)$$

$$I(\sigma^2) = \frac{3}{\sigma^4} E[X^2] - \frac{3}{\sigma^4} E[X] + \frac{3}{4\sigma^4} - \frac{1}{2\pi\sigma^2} \quad (13.7)$$

$$E[X^2] = \sigma^2 + \left(\frac{1}{2}\right)^2 \quad (13.8)$$

$$E[X] = \frac{1}{2} \quad (13.9)$$

$$\Rightarrow I(\sigma^2) = \left(3 - \frac{1}{2\pi}\right) \frac{1}{\sigma^2} \quad (13.10)$$

Hence, Cramér-Rao bound is given as  $\frac{\sigma^2}{(3 - \frac{1}{2\pi})}$

**Definition 13.3:** Variance of  $T$  attains Cramer-Rao lower bound

$\Rightarrow T$  has attained minimum possible variance and  $T$  is an efficient estimator

$X_i$	-1	$-\frac{1}{2}$	1	$\frac{5}{2}$	3
$(X_i - \mu)^2$	$\frac{9}{4}$	1	$\frac{1}{4}$	4	$\frac{25}{4}$

Table 13.1: Table 1

Therefore,

$$T = \frac{\sum (X_i - \mu)^2}{n} \quad (13.11)$$

$$n = 5 \quad (13.12)$$

$$\mu = \frac{1}{2} \quad (13.13)$$

$$\sum (X_i - \mu)^2 = 13.75 \quad (13.14)$$

Hence,

$$T = 2.75 \quad (13.15)$$

Since,  $T$  is an unbiased estimator of  $\sigma^2$ ,

$$\text{Cramér-Rao bound} = \frac{T}{\left(3 - \frac{1}{2\pi}\right)} \quad (13.16)$$

$$= 0.968 \quad (13.17)$$

13.2 Let  $X$  be a random variable with probability density function

$$f(x; \lambda) = \begin{cases} \frac{1}{\lambda} e^{-\frac{x}{\lambda}} & \text{if } x > 0 \\ 0 & \text{otherwise} \end{cases} \quad (13.18)$$

where  $\lambda > 0$  is an unknown parameter. Let  $Y_1, Y_2, \dots, Y_n$  be a random sample of size  $n$

from a population having the same distribution as  $X^2$ . If

$$\bar{Y} = \frac{1}{n} \sum_{i=1}^n Y_i \quad (13.19)$$

then which of the following statements is true?

- (a)  $\sqrt{\frac{\bar{Y}}{2}}$  is a method of moments estimator of  $\lambda$
- (b)  $\sqrt{\bar{Y}}$  is a method of moments estimator of  $\lambda$
- (c)  $\frac{1}{2}\sqrt{\bar{Y}}$  is a method of moments estimator of  $\lambda$
- (d)  $2\sqrt{\bar{Y}}$  is a method of moments estimator of  $\lambda$  (GATE ST 2023)

**Solution:**

- (a) Using PDF in (13.18) we need to find an estimator for the unknown parameter  $\lambda$  in terms of sample mean  $\bar{Y}$

we know  $Y_i = X_i^2$  then,

$$E(Y_i) = E(X_i^2) \quad (13.20)$$

$$= \int_0^\infty x^2 \frac{1}{\lambda} e^{-\frac{x}{\lambda}} \quad (13.21)$$

$$= 2\lambda^2 \quad (13.22)$$

Method of moment is defined by (13.19) which gives,

$$\bar{Y} = E(Y_i) \quad (13.23)$$

$$= 2\lambda^2 \quad (13.24)$$

where

$$\lambda = \sqrt{\frac{\bar{Y}}{2}} \quad (13.25)$$

$\therefore$  Option (13.2a) is correct.

(b) The simulation steps to estimate  $\lambda$  using method of moment estimator in python.

- i. Generate a random value of  $\lambda$  within the specified range using **np.random.uniform(1**
- ii. Use the generated  $\lambda$  to create a random sample of  $X$  values following the given PDF using **np.random.exponential()**
- iii. Then, generate  $Y$  as  $Y = X^2$
- iv. calculate the mean ( $\bar{Y}$ ) as **np.mean(Y)**
- v. Hence, the estimated value of  $\lambda$  is **np.sqrt( $\frac{\bar{Y}}{2}$ )**

Graph of simulated CDF vs Theoretical CDF

13.3 Suppose from the estimation of a linear regression model

$$Y_i = \beta_0 + \beta_1 X_i + e_i$$

the residual sum of squares and the total sum of squares are obtained as 44 and 80, respectively. The value of coefficient of determination is (round off to two decimal places). (GATE XH 2023)

$$Y_i = \beta_0 + \beta_1 X_i + e_i \quad (13.26)$$

Here

**Definition 13.4:** Residual sum of squares(RSS):

Figure 13.1: Figure1

It measures the extent of variability of observed data not predicted by the regression model. That is it estimates the variance in residual or error term's.

$$RSS = \sum (Y_i - \hat{Y}) \quad (13.27)$$

$$= \sum e_i^2 \quad (13.28)$$

$$= \sum (Y_i - \beta_0 - \beta_1 X_i)^2 \quad (13.29)$$

Here  $\hat{Y}$  = the value of Y on the line of regression.

**Definition 13.5:** Total sum of squares(TSS):

Table 13.2: Parameters

Parameters	Description
$Y_i$	Dependent variable
$X_i$	Independent variables
$\beta_0, \beta_1$	Constant variables
$e_i$	Error term

It measures the amount of variation measures in observed data. It is a measure of deviation from the mean. A low total sum of squares indicates little variation between data sets while a higher one indicates more variation.

$$TSS = \sum (Y_i - \bar{Y})^2 \quad (13.30)$$

where  $\bar{Y}$  = Mean of data

**Definition 13.6:** Coefficient of determination( $R^2$ ):

It is the proportion of the variance in the dependent variable that is predicted from the independent variable. It indicates the level of variation in the given data set.

$$R^2 = 1 - \frac{RSS}{TSS} \quad (13.31)$$

$$= 1 - \frac{44}{80} \quad (13.32)$$

$$= 0.45 \quad (13.33)$$

45 percent of the variance in the Y variable is predicted from the X variable.

13.4 Consider the following regression model

$$y_k = \alpha_0 + \alpha_1 \log_e k + \epsilon_k, \quad k = 1, 2, \dots, n,$$

where  $\epsilon_k$ 's are independent and identically distributed random variables each having probability density function  $f(x) = \frac{1}{2}e^{-|x|}$ ,  $x \in \mathbb{R}$ . Then which one of the following statements is true?

- (A) The maximum likelihood estimator of  $\alpha_0$  does not exist
- (B) The maximum likelihood estimator of  $\alpha_1$  does not exist
- (C) The least squares estimator of  $\alpha_0$  exists and is unique
- (D) The least squares estimator of  $\alpha_1$  exists, but it is not unique

(GATE ST 2023)

**Solution:**

$$f(\epsilon_k) = \frac{1}{2}e^{-|\epsilon_k|} \quad (13.34)$$

$$\text{Likelihood function : } f(\epsilon_1 \epsilon_2 \dots \epsilon_n) = \prod_{k=1}^n f(\epsilon_k) \quad (13.35)$$

$$L = \prod_{k=1}^n \frac{1}{2}e^{-|\epsilon_k|} \quad (13.36)$$

$$L_1 = \ln L = \ln \left( \prod_{k=1}^n \frac{1}{2}e^{-|\epsilon_k|} \right) \quad (13.37)$$

$$= \sum_{k=1}^n \ln \left( \frac{1}{2}e^{-|\epsilon_k|} \right) \quad (13.38)$$

$$= \sum_{k=1}^n (-\ln 2 - |y_k - \alpha_0 - \alpha_1 \log_e k|) \quad (13.39)$$

$$= -n \ln 2 - \sum_{k=1}^n (|y_k - \alpha_0 - \alpha_1 \log_e k|) \quad (13.40)$$

$$L_1 = \text{function of } \alpha_0, \alpha_1 \quad (13.41)$$

(a) Maximum likelihood estimator

We need to find the value of  $\alpha_0$  and  $\alpha_1$  which will maximise the value of  $L_1$  i.e. the value of  $\alpha_0$  and  $\alpha_1$  which will minimise the value of  $\sum_{k=1}^n |y_k - \alpha_0 - \alpha_1 \log_e k|$

i. With respect to  $\alpha_0$

A. For  $y_k - \alpha_0 - \alpha_1 \log_e k > 0$

$$\begin{aligned} \min_{\alpha_0} \quad & y_k - \alpha_0 - \alpha_1 \log_e k \\ \text{s.t.} \quad & \alpha_0 \leq y_k - \alpha_1 \log_e k \end{aligned}$$

Using Lagrange multiplier method

$$L(\lambda) = y_k - \alpha_0 - \alpha_1 \log_e k - \lambda(\alpha_0 - y_k + \alpha_1 \log_e k) \quad (13.42)$$

$$\frac{\partial L}{\partial \alpha_0} = -1 - \lambda = 0 \quad (13.43)$$

$$\frac{\partial L}{\partial \lambda} = y_k - \alpha_0 - \alpha_1 \log_e k = 0 \quad (13.44)$$

$$\lambda = -1 \quad (13.45)$$

$$\alpha_0 = y_k - \alpha_1 \log_e k \quad (13.46)$$

B. For  $y_k - \alpha_0 - \alpha_1 \log_e k < 0$

$$\min_{\alpha_0} \quad -(y_k - \alpha_0 - \alpha_1 \log_e k)$$

$$\text{s.t.} \quad \alpha_0 \geq y_k - \alpha_1 \log_e k$$

Using Lagrange multiplier method

$$L(\lambda) = -(y_k - \alpha_0 - \alpha_1 \log_e k) - \lambda(\alpha_0 - y_k + \alpha_1 \log_e k) \quad (13.47)$$

$$\frac{\partial L}{\partial \alpha_0} = 1 - \lambda = 0 \quad (13.48)$$

$$\frac{\partial L}{\partial \lambda} = y_k - \alpha_0 - \alpha_1 \log_e k = 0 \quad (13.49)$$

$$\lambda = 1 \quad (13.50)$$

$$\alpha_0 = y_k - \alpha_1 \log_e k \quad (13.51)$$

As value of  $\alpha_0$  matches for both cases of modulus

$\therefore$  The maximum likelihood estimator of  $\alpha_0$  exist

ii. With respect to  $\alpha_1$

A. For  $y_k - \alpha_0 - \alpha_1 \log_e k > 0$

$$\begin{aligned} \min_{\alpha_1} \quad & y_k - \alpha_0 - \alpha_1 \log_e k \\ \text{s.t.} \quad & \alpha_1 \leq \frac{y_k - \alpha_0}{\log_e k} \end{aligned}$$

Using Lagrange multiplier method

$$L(\lambda) = y_k - \alpha_0 - \alpha_1 \log_e k - \lambda \left( \alpha_1 - \frac{y_k - \alpha_0}{\log_e k} \right) \quad (13.52)$$

$$\frac{\partial L}{\partial \alpha_1} = -\log_e k - \lambda = 0 \quad (13.53)$$

$$\frac{\partial L}{\partial \lambda} = - \left( \alpha_1 - \frac{y_k - \alpha_0}{\log_e k} \right) = 0 \quad (13.54)$$

$$\lambda = -\log_e k \quad (13.55)$$

$$\alpha_1 = \frac{y_k - \alpha_0}{\log_e k} \quad (13.56)$$

B. For  $y_k - \alpha_0 - \alpha_1 \log_e k < 0$

$$\begin{aligned} \min_{\alpha_1} \quad & -(y_k - \alpha_0 - \alpha_1 \log_e k) \\ \text{s.t.} \quad & \alpha_1 \geq \frac{y_k - \alpha_0}{\log_e k} \end{aligned}$$

Using Lagrange multiplier method

$$L(\lambda) = -(y_k - \alpha_0 - \alpha_1 \log_e k) - \lambda \left( \alpha_1 - \frac{y_k - \alpha_0}{\log_e k} \right) \quad (13.57)$$

$$\frac{\partial L}{\partial \alpha_1} = \log_e k - \lambda = 0 \quad (13.58)$$

$$\frac{\partial L}{\partial \lambda} = - \left( \alpha_1 - \frac{y_k - \alpha_0}{\log_e k} \right) = 0 \quad (13.59)$$

$$\lambda = \log_e k \quad (13.60)$$

$$\alpha_1 = \frac{y_k - \alpha_0}{\log_e k} \quad (13.61)$$

As value of  $\alpha_1$  matches for both cases of modulus

$\therefore$  The maximum likelihood estimator of  $\alpha_1$  exist

$\therefore$  Option (A) and (B) are incorrect

iii. Least square estimator

The least square estimator of  $\alpha_0$  and  $\alpha_1$  is  $\tilde{\alpha}_0$  and  $\tilde{\alpha}_1$  which will minimise

parameter	value	description
$\bar{y}$	$\frac{1}{n} \sum_{k=1}^n y_k$	Average value of $y_k$
$\bar{x}$	$\frac{1}{n} \sum_{k=1}^n \log_e k$	Average value of $\log_e k$

Table 13.3: Variables used

$$Q(\alpha_0, \alpha_1) = \sum_{k=1}^n (y_k - \alpha_0 - \alpha_1 \log_e k)^2 \quad (13.62)$$

$$\frac{\partial Q}{\partial \alpha_0} = -2 \sum_{k=1}^n (y_k - \alpha_0 - \alpha_1 \log_e k) = 0 \quad (13.63)$$

$$\sum_{k=1}^n (y_k - \alpha_0 - \alpha_1 \log_e k) = 0 \quad (13.64)$$

$$n\bar{y} - n\alpha_0 - \alpha_1 n\bar{x} = 0 \quad (13.65)$$

$$\implies \tilde{\alpha}_0 = \bar{y} - \tilde{\alpha}_1 \bar{x} \quad (13.66)$$

$$\frac{\partial Q}{\partial \alpha_1} = -2 \sum_{k=1}^n (y_k - \alpha_0 - \alpha_1 \log_e k) \log_e k = 0 \quad (13.67)$$

$$\implies \tilde{\alpha}_1 = \frac{\sum_{k=1}^n (\log_e k - \bar{x})(y_k - \bar{y})}{\sum_{k=1}^n (\log_e k - \bar{x})^2} \quad (13.68)$$

$\therefore$  Least square estimator of  $\alpha_0$  and  $\alpha_1$  exists and are unique

$\therefore$  Option (C) is correct and (D) is incorrect

iv. Steps for simulation the given distribution whose probability density function

is  $f(x) = \frac{1}{2}e^{-|x|}$

A. Write a function cdf for calculating the cdf of any random variable

$$p_X(x) = \begin{cases} \frac{1}{2}e^x & x \leq 0 \\ \frac{1}{2}e^{-x} & x > 0 \end{cases} \quad (13.69)$$

$$F_X(x) = \begin{cases} \int_{-\infty}^x \left(\frac{1}{2}e^x\right) dx & x \leq 0 \\ \int_{-\infty}^0 \left(\frac{1}{2}e^x\right) dx + \int_0^x \left(\frac{1}{2}e^{-x}\right) dx & x > 0 \end{cases} \quad (13.70)$$

$$F_X(x) = \begin{cases} \frac{1}{2}e^x & x \leq 0 \\ \frac{1}{2}(2 - e^{-x}) & x > 0 \end{cases} \quad (13.71)$$

B. Declare a function inverse cdf ( $I(u)$ ) such that its input is any random number and output is random variable whose cdf equals that of the given distribution

For  $x \leq 0$

$$u = \frac{1}{2}e^x \quad (13.72)$$

$$e^x = 2u \quad (13.73)$$

$$x = \ln 2u \quad (13.74)$$

$$\because x \leq 0 \quad (13.75)$$

$$u \leq 0.5 \quad (13.76)$$

For  $x > 0$

$$u = \frac{1}{2}(2 - e^{-x}) \quad (13.77)$$

$$2 - e^{-x} = 2u \quad (13.78)$$

$$e^{-x} = 2 - 2u \quad (13.79)$$

$$x = -\ln(2 - 2u) \quad (13.80)$$

$$\because x > 0 \quad (13.81)$$

$$u > 0.5 \quad (13.82)$$

$$I(u) = \begin{cases} \ln(2u) & u \leq 0.5 \\ -\ln(2-2u) & u > 0.5 \end{cases} \quad (13.83)$$

- C. Define three arrays `random_vars` , `cdf_values` , `theoretical_cdf_values` to store random variables, simulated cdf values and theoretical cdf values
- D. Generate random numbers using `rand()` and calling inverse cdf function to generate our random variable
- E. Calling cdf function to calculate the cdf of the generated random variable
- F. Storing the random variable, theoretical cdf and generated cdf into their respective arrays
- G. Storing the data of these three array into a `.dat` file
- H. Plotting these `.dat` file in python

13.5 Consider the following regression model

$$y_t = \alpha_0 + \alpha_1 t + \alpha_2 t^2 + \epsilon_t, \quad t = 1, 2, \dots, n \quad (13.84)$$

where  $\alpha_0$  ,  $\alpha_1$  and  $\alpha_2$  are unknown parameters and  $\epsilon_t$ 's are independent and identically distributed random variables each having  $\mathcal{N}(\mu, 1)$  distribution with  $\mu$  unknown. Then which of the following statements is/are true?

- (a) There exists an unbiased estimator of  $\alpha_1$
- (b) There exists an unbiased estimator of  $\alpha_2$
- (c) There exists an unbiased estimator of  $\alpha_0$
- (d) There exists an unbiased estimator of  $\mu$

(GATE ST 2023)

**Solution:** Assuming that the model is

$$y_t = \alpha_0 + \alpha_1 t + \alpha_2 t^2 + \epsilon_t \quad (13.85)$$

$$\begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix} = \begin{bmatrix} 1 & A_{11} & A_{12} \\ 1 & A_{21} & A_{22} \\ \vdots & & \\ 1 & A_{n1} & A_{n2} \end{bmatrix} \begin{bmatrix} \alpha_0 \\ \alpha_1 \\ \alpha_2 \end{bmatrix} + \begin{bmatrix} \epsilon_1 \\ \epsilon_2 \\ \vdots \\ \epsilon_n \end{bmatrix} \quad (13.86)$$

Finding mean of the  $\mathbf{y}$ ,

$$\mathbf{y} = \mathbf{A}\mathbf{a} + \boldsymbol{\epsilon} \quad (13.87)$$

$$E(\mathbf{y}) = E(\mathbf{A}\mathbf{a} + \boldsymbol{\epsilon}) \quad (13.88)$$

$$= \mathbf{A}\mathbf{a} + E(\boldsymbol{\epsilon}) \quad (13.89)$$

$$E(\boldsymbol{\epsilon}) = \begin{bmatrix} E(\epsilon_1) \\ E(\epsilon_2) \\ \cdot \\ \cdot \\ E(\epsilon_n) \end{bmatrix} = \begin{bmatrix} \mu \\ \mu \\ \cdot \\ \cdot \\ \mu \end{bmatrix} \quad (13.90)$$

$$\boldsymbol{\mu}_\epsilon = \mu \begin{bmatrix} 1 \\ 1 \\ \cdot \\ \cdot \\ 1 \end{bmatrix} \quad (13.91)$$

Let  $\mathbf{A}_i$  represent the  $i^{th}$  row of  $\mathbf{A}$

$$\text{Cov}(y_i, y_j) = E((y_i - E(y_i))(y_j - E(y_j))) \quad (13.92)$$

$$= E((\mathbf{A}_i \mathbf{a} + \epsilon_i - E(\mathbf{A}_i \mathbf{a} + \epsilon_i))(\mathbf{A}_j \mathbf{a} + \epsilon_j - E(\mathbf{A}_j \mathbf{a} + \epsilon_j))) \quad (13.93)$$

$$= E((\epsilon_i - E(\epsilon_i))(\epsilon_j - E(\epsilon_j))) \quad (13.94)$$

$$= \text{Cov}(\epsilon_i, \epsilon_j) \quad (13.95)$$

$$\mathbf{C}_y = \mathbf{C}_\epsilon \quad (13.96)$$

Since the  $\epsilon_i$ 's are independent and identical vectors,

$$\text{Cov}(\epsilon_i, \epsilon_j) = 0, \quad \forall i \neq j \quad (13.97)$$

$$\text{Var}(\epsilon_i) = 1, \quad \forall 1 \leq i \leq n \quad (13.98)$$

$$\mathbf{C}_{\mathbf{y}} = I_{n \times n} \quad (13.99)$$

$$\mathbf{y} \sim \mathcal{N}(\mathbf{A}\mathbf{a} + \boldsymbol{\mu}_{\epsilon}, I) \quad (13.100)$$

$$p_{\mathbf{y}} = \frac{1}{\sqrt{(2\pi)^n \det(\mathbf{C}_{\mathbf{y}})}} \exp \frac{-(\mathbf{y} - \boldsymbol{\mu}_{\epsilon} - \mathbf{A}\mathbf{a})^T \mathbf{C}_{\mathbf{y}}^{-1} (\mathbf{y} - \boldsymbol{\mu}_{\epsilon} - \mathbf{A}\mathbf{a})}{2} \quad (13.101)$$

where  $\mathbf{C}_{\mathbf{y}}$  is the covariance matrix for  $\mathbf{y}$

The maximum likelihood function can be written as:

$$L(\mathbf{y}) = \frac{1}{(2\pi)^{\frac{n}{2}}} e^{\frac{-(\mathbf{y} - \boldsymbol{\mu}_{\epsilon} - \mathbf{A}\mathbf{a})^T (\mathbf{y} - \boldsymbol{\mu}_{\epsilon} - \mathbf{A}\mathbf{a})}{2}} \quad (13.102)$$

$$\ln L(\mathbf{y}) = -\frac{n}{2} \ln(2\pi) - \frac{1}{2} (\mathbf{y} - \boldsymbol{\mu}_{\epsilon} - \mathbf{A}\mathbf{a})^T (\mathbf{y} - \boldsymbol{\mu}_{\epsilon} - \mathbf{A}\mathbf{a}) \quad (13.103)$$

$$\frac{\partial \ln L(\mathbf{y})}{\partial \mathbf{a}} = \frac{\partial (-\mathbf{y}^T \mathbf{A}\mathbf{a} - \mathbf{a}^T \mathbf{A}^T \mathbf{y} + \mathbf{a}^T \mathbf{A}^T \mathbf{A}\mathbf{a} + \mathbf{a}^T \mathbf{A}^T \boldsymbol{\mu}_{\epsilon} + \boldsymbol{\mu}_{\epsilon}^T \mathbf{A}\mathbf{a})}{\partial \mathbf{a}} \quad (13.104)$$

$$= -2\mathbf{A}^T \mathbf{y} + 2\mathbf{A}^T \mathbf{A}\mathbf{a} + 2\mathbf{A}^T \boldsymbol{\mu}_{\epsilon} \quad (13.105)$$

The normal equation is

$$\frac{\partial \ln L(\mathbf{y})}{\partial \mathbf{a}} = 0 \quad (13.106)$$

$$\mathbf{a} = (\mathbf{A}^T \mathbf{A})^{-1} (\mathbf{A}^T \mathbf{y} - \mathbf{A}^T \boldsymbol{\mu}_{\epsilon}) \quad (13.107)$$

For unbiased estimator,

$$E(\mathbf{a}) = \mathbf{a} \quad (13.108)$$

$$E(\mathbf{a}) = E\left((\mathbf{A}^T \mathbf{A})^{-1} (\mathbf{A}^T \mathbf{y} - \mathbf{A}^T \boldsymbol{\mu}_\epsilon)\right) \quad (13.109)$$

$$= (\mathbf{A}^T \mathbf{A})^{-1} (\mathbf{A}^T E(\mathbf{y}) - \mathbf{A}^T \boldsymbol{\mu}_\epsilon) \quad (13.110)$$

$$= (\mathbf{A}^T \mathbf{A})^{-1} (\mathbf{A}^T (\mathbf{A} \mathbf{a} + \boldsymbol{\mu}_\epsilon) - \mathbf{A}^T \boldsymbol{\mu}_\epsilon) \quad (13.111)$$

$$= (\mathbf{A}^T \mathbf{A})^{-1} (\mathbf{A}^T \mathbf{A}) \mathbf{a} \quad (13.112)$$

$$= \mathbf{a} \quad (13.113)$$

Hence there exist unbiased estimator for  $\alpha_0, \alpha_1, \alpha_2$

For Maximum Likelihood Estimator of  $\mu$

$$\frac{\partial \ln L(\mathbf{y})}{\partial \boldsymbol{\mu}_\epsilon} = \frac{\partial (-\mathbf{y}^T \boldsymbol{\mu}_\epsilon - \mathbf{a}^T \mathbf{A}^T \boldsymbol{\mu}_\epsilon + \boldsymbol{\mu}_\epsilon^T \mathbf{y} + \boldsymbol{\mu}_\epsilon^T \mathbf{A} \mathbf{x} + \boldsymbol{\mu}_\epsilon^T \boldsymbol{\mu}_\epsilon)}{\partial \boldsymbol{\mu}_\epsilon} \quad (13.114)$$

$$= -2\mathbf{y} + 2\mathbf{A} \mathbf{a} + 2\boldsymbol{\mu}_\epsilon \quad (13.115)$$

The normal equation is

$$\frac{\partial \ln L(\mathbf{y})}{\partial \boldsymbol{\mu}_\epsilon} = 0 \quad (13.116)$$

$$\boldsymbol{\mu}_\epsilon = \mathbf{y} - \mathbf{A} \mathbf{a} \quad (13.117)$$

$$E(\boldsymbol{\mu}_\epsilon) = E(\mathbf{y} - \mathbf{A}\mathbf{a}) \quad (13.118)$$

$$= E(\mathbf{y}) - \mathbf{A}\mathbf{a} \quad (13.119)$$

$$= E(\boldsymbol{\epsilon}) \quad (13.120)$$

$$= \boldsymbol{\mu}_\epsilon \quad (13.121)$$

Since,

$$\boldsymbol{\mu}_\epsilon = \mu \begin{bmatrix} 1 \\ 1 \\ \cdot \\ \cdot \\ \cdot \\ 1 \end{bmatrix} \quad (13.122)$$

Hence there exists an unbiased estimator for  $\mu$  as well.

Simulation in C We get the following values:

Parameter	True Value	Simulated Value	Average Bias
$\alpha_0$	3	2.983275	0.016725
$\alpha_1$	2	2.002000	-0.002000
$\alpha_2$	0.5	0.500500	-0.000500
$\mu$	0.1	0.1	0

Table 13.4: Simulation results

- Defining some arbitrary values for  $\alpha_0, \alpha_1, \alpha_2$  and  $\mu$
- Generating the epsilon using Box-Muller method and using it to find  $y_i$
- Generating dependent variable  $y_i$  using  $y_i = \alpha_0 + \alpha_1 i + \alpha_2 i^2 + \epsilon_i, \quad i = 1, 2, \dots, n$

- (d) Storing the generated data into a *generated\_data.dat* file.
- (e)  $\epsilon_i$  is generated as a gaussian variable
- (f) Defining 4 variables *beta<sub>0</sub>hat*, *beta<sub>1</sub>hat*, *beta<sub>2</sub>hat* and *mu – hat* for string the estimated values
- (g) Defining 4 variables *beta<sub>0</sub>bias*, *beta<sub>1</sub>bias*, *beta<sub>2</sub>bias* and *mu – bias* for keeping track of the deviation of the estimated values from the true values
- (h) Using nested for loops to ensure that average bias for each coefficient is calculated over multiple simulations
- (i) Dividing the total bias by the number of simulations to get the average bias per simulation

## Chapter 14

# Multivariate Gaussian

14.1 Suppose that  $(\mathbf{X}_1, \mathbf{X}_2, \mathbf{X}_3)$  has  $N_3(\mu, \Sigma)$  distribution with  $\mu = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$   $\Sigma = \begin{bmatrix} 2 & 2 & 1 \\ 2 & 5 & 1 \\ 1 & 1 & 1 \end{bmatrix}$

Given that  $\phi(-0.5)=0.3085$ , where  $\phi(\cdot)$  denotes the cumulative distribution function of a standard normal random variable,  $P\left((X_1 - 2X_2 + 2X_3)^2 < \frac{7}{2}\right)$  equals to  
(GATE ST 2023)

**Solution:**

$$\text{Let } \mathbf{Y} = \mathbf{X}_1 - 2\mathbf{X}_2 + 2\mathbf{X}_3 \text{ and } \mathbf{a} = \begin{bmatrix} 1 \\ -2 \\ 2 \end{bmatrix}$$

$$\mu_Y = \mathbf{a}^T \boldsymbol{\mu} \quad (14.1)$$

$$= \begin{bmatrix} 1 & -2 & 2 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \quad (14.2)$$

$$= 0 \quad (14.3)$$

$$\sigma_Y^2 = \mathbf{a}^T \boldsymbol{\Sigma} \mathbf{a} \quad (14.4)$$

$$= \begin{bmatrix} 1 & -2 & 2 \end{bmatrix} \begin{bmatrix} 2 & 2 & 1 \\ 2 & 5 & 1 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ -2 \\ 2 \end{bmatrix} \quad (14.5)$$

$$= 1 \quad (14.6)$$

$$\Pr \left( Y^2 < \frac{7}{2} \right) = \Pr \left( -\sqrt{\frac{7}{2}} < Y < \sqrt{\frac{7}{2}} \right) \quad (14.7)$$

$$\Phi(x) = \int_{-\infty}^x \frac{1}{\sqrt{2\pi}} e^{-\frac{z^2}{2}} dz \quad (14.8)$$

$$\Phi \left( \sqrt{\frac{7}{2}} \right) = \int_{-\infty}^{\sqrt{\frac{7}{2}}} \frac{1}{\sqrt{2\pi}} e^{-\frac{z^2}{2}} dz \quad (14.9)$$

$$= \int_{-\infty}^{-\frac{1}{2}} \frac{1}{\sqrt{2\pi}} e^{-\frac{z^2}{2}} + \int_{-\frac{1}{2}}^{\sqrt{\frac{7}{2}}} \frac{1}{\sqrt{2\pi}} e^{-\frac{z^2}{2}} dz \quad (14.10)$$

$$= \Phi(-0.5) + \int_{-\frac{1}{2}}^{\sqrt{\frac{7}{2}}} \frac{1}{\sqrt{2\pi}} e^{-\frac{z^2}{2}} dz \quad (14.11)$$

$$= 0.3085 + 0.66082 \quad (14.12)$$

$$= 0.96932 \quad (14.13)$$

$$\Phi\left(-\sqrt{\frac{7}{2}}\right) = \int_{-\infty}^{-\sqrt{\frac{7}{2}}} \frac{1}{\sqrt{2\pi}} e^{-\frac{z^2}{2}} dz \quad (14.14)$$

$$= 0.03068 \quad (14.15)$$

$$\Pr\left(\left(X_1 - 2X_2 + 2X_3\right)^2 < \frac{7}{2}\right) = \Phi\left(\sqrt{\frac{7}{2}}\right) - \Phi\left(-\sqrt{\frac{7}{2}}\right) \quad (14.16)$$

$$= 0.96932 - 0.03068 \quad (14.17)$$

$$= 0.93864 \quad (14.18)$$

## 14.1. Simulation Steps

- (a) Generate Random Samples: Generate random samples for  $X_1$ ,  $X_2$ , and  $X_3$  from the given multivariate normal distribution with mean vector  $\mu = [0, 0, 0]$  and covariance matrix  $\Sigma$ .
- (b) Calculate  $Y$ : Calculate  $Y = X_1 - 2X_2 + 2X_3$ .
- (c) Count Samples: Count the number of samples for which  $Y^2 < \frac{7}{2}$ .
- (d) Calculate Estimated Probability: Calculate the estimated probability by dividing the count by the total number of samples (1000000).
